Operation was performed as an emergency measure about two hours after the pupil became dilated and fixed, and a compact mass composed of four heavily encapsulated abscesses was removed *en bloc* from the inferior portion of the right frontal lobe. Although there was slight general improvement following operation, the patient did not recover consciousness, and he died on the fifth postoperative day. During the postoperative period the right pupil remained semidilated, and it was noted that the right eye did not move as freely as the left.

At necropsy there was herniation of both hippocampal gyri over the free edges of the tentorium cerebelli. This was more marked on the right side, and the right oculomotor nerve was discolored at the point of compression. There was an area of infarction in the medial aspect of the right occipital lobe. In spite of the fact that one of the abscesses was opened and evacuated at the time of the operation, there was no evidence of meningitis or infection of the wound.

The extradural compression in the experimental acute herniations was obtained through the use of a Forbes window screwed tightly into a trephine hole in the skull, the position of which varied in different animals between the frontal, parietal and temporal regions. After the dura had been separated from the calvarium for a short distance around the trephine hole, Ringer's solution was allowed to flow in, and the pressure exerted could be altered and recorded at all times. The animals were under light dial anesthesia with the head held in the Gage head holder.

It was possible to produce at will ipsilateral pupillary dilatation and to watch the pupil return to normal on release of the pressure. After the pressure had been kept at a level sufficiently high to hold the pupil in complete dilatation and fixation, the animals were killed. Ipsilateral hippocampal herniation was found as a routine at necropsy. The herniation was great in the animals showing marked pupillary change and less extreme in those showing lesser degrees of involvement of the third nerve. The following is a representative result of an experiment in acute compression:

Fig 5.—A typical result in an experiment in chronic compression (experiment 2) *A*, dilated and fixed pupil in the conscious animal, the result of ipsilateral cerebral compression *B*, dilated and fixed pupil and ptosis at a later period when pressure had become greater *C*, dissection with accurate tracing below showing the artificial extradural expanding lesion (*S*), the herniation (*X*) of the hippocampal gyrus (*H*) over the free edge of the tentorium (*T*). More anteriorly the herniation was pressing on the third nerve (*3*).

EXPERIMENT 1.—A trephine hole was made in the left frontoparietal region and the Forbes window screwed in (fig. 4). The extradural pressure was started at 40 mm. of mercury and gradually raised to 90 mm. of mercury during the next hour. Three and one-half hours after the experiment was started the ipsilateral pupil began to dilate and soon became fully dilated and fixed. Whenever the pressure was lowered the pupil rapidly returned to normal and again dilated when the pressure was increased. This procedure was carried out many times with the same result. The pressure was then kept at 90 mm. of mercury for eight hours, at the end of which time the animal was killed. At necropsy a herniation of the hippocampal gyrus was found over the anterior end of the tentorium pressing on the third nerve.

In order to produce chronic extradural compression that would be progressive, the dura was stripped from the calvarium and a hygroscopic material, either recently moistened saraka seeds or gum tragacanth, was packed between the bone and the dura. The trephine opening was then closed by screwing a tight-fitting, threaded, flat metal disk into it. The scalp was sutured and the animal, after recovering from the anesthetic, was carefully observed. Again, when ipsilateral dilatation was present, hippocampal herniation was found and the degree of palsy of the third nerve was dependent on the amount of herniation present. In none of the experimental animals did we find infarctions or hemorrhages. The first signs of dilatation of the pupil developed in these animals in the group with chronic compression from seven to thirty-six hours after the extradural compression was started. The animal in experiment 2 showed the first pupillary changes twenty-six hours after operation.

EXPERIMENT 2.—The dura was stripped around a trephine hole over the left temporoparietal region and saraka seeds were packed into the space made (fig. 5). During the next twenty-four hours the left pupil varied in size and was erratic in its reaction. At twenty-six hours it had begun to dilate and at thirty-four hours it was fully dilated and fixed, and there was ptosis of the left upper lid. The animal died at the end of forty-nine hours and at necropsy there was a marked herniation of the ipsilateral hippocampal gyrus over the free edge of the tentorium. This herniation was pressing firmly on the third nerve and by displacing the midbrain to the right it had put the nerve on the stretch.

COMMENT

From a study of ten patients with unilateral expanding cerebral lesions, eight of these at autopsy and ten experiments on monkeys, we have concluded that herniation of the hippocampal gyrus over the free edge of the tentorium by its pressure on the third nerve as it crosses the greater wing of the sphenoid bone can cause paresis or complete paralysis of this nerve. As evidence of the amount of pressure which the herniation is capable of producing, we have cited the interference with circulation through the posterior cerebral artery with resulting infarction of the brain in the area supplied by it.

We recognize and have studied some of the other pathologic alterations that are associated with herniations through the incisura tentorii; ipsilateral hemiplegia reported by Kernohan and Woltman [7] and by Hoen [8] and midbrain hemorrhage,[9] conditions which were not present in the cases under discussion and were not produced in our experiments.

From the literature and in discussion with others, many valuable suggestions have been obtained, shaping our work and influencing the conclusions. Our experiments, it seems to us, are more precise and the results more conclusive than those reported by Hoessly.[5] Meyer [6] and Vincent, David and Thiébaut [10] have made hippocampal herniations familiar, but they have not pointed out the associated involvement of the third nerve that has been such a striking feature in the cases and experiments we report. Mr. Geoffrey Jefferson of Manchester, England, in a verbal communication stated that he had reached the conclusion that pupillary dilatation in ipsilateral expanding cerebral lesions was due to pressure on the third nerve by the herniated gyrus and that he had removed the gyrus and had seen palsy of the third nerve clear postoperatively.

With the herniation there is distortion of the midbrain, and the question arises as to whether or not disorders of the third nerve could result from nuclear disturbances. The work of Magoun, Atlas, Hare and Ranson [11] and of Crouch [12] has helped to localize the site of the lesion. The former group of investigators obtained bilateral pupillary constriction on stimulation of points around the central gray matter of the midbrain up to the nucleus of the third nerve, but ipsilateral pupillary constriction was obtained only when they stimulated points peripheral to the nucleus. From this they concluded that there was a final partial decussation of pupillary reflex fibers in the immediate vicinity of the nucleus of the third nerve. Crouch [12] showed that each third nerve receives the majority of its fibers from the nucleus of the same side but that it receives also a certain number of fibers from the opposite nucleus. From the evidence produced by these investigators it is clear that a lesion causing one dilated and fixed pupil must lie peripheral to the nucleus and the absence of other midbrain signs would place it in the peripheral part of the third nerve. Each clinical and experimental case that we have included has presented such a lesion in the form of a herniated hippocampal gyrus pressing on the third nerve. In some of our cases the nerve was flattened or stretched and in one instance discolored.

The amount of pressure necessary to produce the herniation in the normal animal may give some idea of the pressure in cases in human beings when these herniations occur. In some of the animals it was almost as high as the systolic blood pressure, and this may aid in the explanation of the infarctions that occur in cases in man. Thus, from the clinical standpoint, when ipsilateral fixed dilatation of the pupil is present, the situation is a very grave one. If the mechanism causing the herniation is allowed to continue to act or even if the herniation is not removed after the primary expanding lesion is corrected, cerebral infarctions, pontile hemorrhages, damage to the contralateral peduncle, distortion of the midbrain and aqueduct block may occur.

Why all cases in which death is caused by increased intracranial pressure due to a supratentorial expanding

lesion do not show herniation as a routine and one or even all of the complications which can result, we cannot say. Since we have become more familiar with the condition at the autopsy table and have been more on the alert for the clinical manifestations, both its clinical recognition, as the result of close watch of the dying patient, and its postmortem occurrence have been more frequently recorded.

CONCLUSIONS

Herniation of the hippocampal gyrus over the free edge of the tentorium due to an ipsilateral expanding cerebral lesion can cause pressure on the third nerve as it crosses the body of the sphenoid bone sufficient to paralyze this nerve partially or completely. The dilated and fixed pupil usually is the earliest clinical sign of the herniation. The involvement of the third nerve, however, may be but one of the manifestations of the herniation. It is a danger sign not only in intracerebral space-occupying lesions but in extradural and subdural ones as well. It is emphasized in this paper because, if its significance is appreciated early, treatment may prevent the other complications.

THE INCIDENCE OF MAJOR ALLERGIC DISEASES IN COLORADO SPRINGS

W. C. SERVICE, M.D.
COLORADO SPRINGS, COLO.

A survey of the city of Colorado Springs with regard to the incidence of the major allergic diseases was undertaken during the last twelve months. The general impression among the physicians of this city during the last few years has been that there was a decided increase in the prevalence of hay fever and asthma. Colorado Springs and its environs have long been a mecca for health seekers. This community is widely noted for its beautiful and comfortable homes, broad clean streets, supervised play grounds and well developed public utilities. It is a center of culture, education and recreation, as distinguished from a community characterized primarily by industrial, commercial or service factors.

The population is to a large extent native born, the chief foreign groups being English, German and Canadian. There is more than the average preponderance of females over males and a larger proportion of persons in the later age groups than is characteristic of the United States as a whole.

The climate is moderately cool, with low precipitation, low humidity and a high percentage of sunshine. The mean average temperature over a fourteen year period was 48.1 F. The mean relative humidity was 46.78 per cent, and there were 13.2 inches of precipitation and 60.6 per cent of sunshine.

The city has a population of 35,000 and is situated at the foothills of the Rampart range of the Rocky Mountains at an elevation of 6,000 feet above sea level. A botanic survey of this region with the pollination periods has been previously published.[1]

On the advice of the director of the Cowles Commission for Economic Research, the city was divided into five economic districts. This was done in order to obtain the most accurate cross section of the population. The districts selected gave about equal numbers of persons in each economic group. The survey was conducted through a house to house canvass by two men from the department of biology at Colorado College whom I trained. Whenever a questionable case was encountered I investigated it.

The investigation related to the occurrence of major allergies in the general population. The minor allergies, in which the subject had recognized an allergic reaction to a specific substance with which he came in contact only occasionally, were not tabulated. The persons with minor allergies had not found it necessary to seek medical relief for their symptoms, since by avoiding the specific substances they were able to obtain complete relief. All persons with major allergies had found it necessary to seek medical relief, although in many cases a complete diagnostic allergic study had not been undertaken.

The major allergic conditions investigated were grouped under the headings hay fever, asthma, eczema, migraine, urticaria and gastrointestinal allergy. One thousand families were investigated, 200 from each of the five economic districts. These comprised a total of 3,141 persons. In reviewing the available medical literature on the incidence of allergic diseases in the United States, Coca [2] estimated the incidence of hay fever to be less than 1 per cent in the general population. Scheppegrell [3] concluded that about 1.5 per cent of the general population suffered from hay fever. Cooke and Spain [4] said that from 3 to 5 per cent of the population of New York and its vicinity had hay fever and asthma. Piness and Miller [5] reported a study on two controlled communities; the incidence of hay fever was 4.4 per cent in one and was estimated at between 3 and 4 per cent in the other, although only 1.5 per cent of the population presented themselves for treatment. Cooke and Vander Vere [6] reported about 7 per cent of the population suffering from hypersensitiveness, including even the minor degrees of sensitization. Jimenez [7] reported that 11.9 per cent of the incoming students at the University of Michigan have had eczema, hay fever or asthma. An additional 22 per cent presented a history of allergic manifestations accompanied by a family history of sensitization. Rowe [8] reported that of 400 university students 35 per cent had a personal history of probable allergy. Vaughan [9] reported that upward of 10 per cent of the population have major allergic manifestations, usually subacute or chronic, and approximately 50 per cent give a history of minor episodic allergic manifestations. Pipes [10] reported that approximately 13 per cent of the population are subject to major allergic manifestations and that 36 per cent describe minor allergic reactions.

Because of the discrepancies in the reports encountered in the literature and a belief that a survey of a

larger number of cases would justify more definite conclusions, this survey of Colorado Springs was undertaken.

SURVEY

One thousand families were investigated, and 505, or 50.5 per cent, had one or more members who evidenced major allergic manifestations. Among the 3,141 persons interviewed 711, or 22.6 per cent, presented 842 major allergic manifestations, approximately 16 per cent showing more than one. A series of studies was carried out in each of the six groups.

Hay Fever.—Of the 3,141 persons interviewed, 316 had hay fever. This is an incidence of 10.06 per cent for hay fever in the general population. Of this number forty-eight, or 15.2 per cent, had had hay fever before coming to Colorado, which leaves 8.5 per cent of the population who acquired it locally. Every person in this group had sought medical treatment for the relief of symptoms. However, only 30 per cent had received adequate allergic diagnosis and treatment. The remaining 70 per cent had sought relief in different ways, including local treatments of the nose, eyes and throat, nonspecific protein injections, cauterization, and mixed pollen injections without tests and without any adequate allergic program. Pollen was given as the cause of the trouble by 89 per cent, epidermals and dust by 3.5 per cent and food by 3.5 per cent; for the remaining 4 per cent the cause was unknown.

The ages of the hay fever patients varied from 1 to 65 years. The distribution according to the age of onset and the duration are reported in table 1 and chart 1.

TABLE 1.—*Distribution of Hay Fever*

Age, Years	No of Cases	Per Cent	Average Age at Onset, Years	Average Duration, Years	Per Cent Duration
0-10	98	31	5 6	14 3	45 5
10-20	83	26	13 4	16 3	30 1
20-30	59	19	24 4	14 0	16 0
30-40	49	15	33 8	12 9	7 0
40 50	23	8	42 9	12 3	1 4
50-60	3	1	52 2	7 6	. .
60-70	1		65 0	5 0	. ..

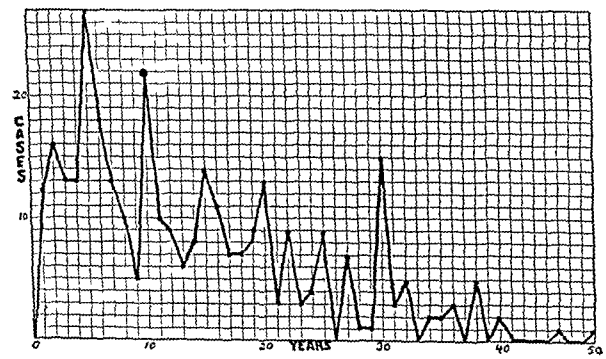

Chart 1.—Duration of hay fever.

The figures indicate that hay fever tends to manifest itself in childhood, almost 60 per cent of the patients having acquired the condition before the age of 20. There is a fall in the occurrence and in the duration in each decade. The average duration for each of the ten year periods is practically the same. Of the hay fever sufferers, 58 per cent were males and 42 per cent females.

Asthma.—Among the 3,141 persons investigated 114 had asthma. This represents an incidence of asthma in the general population of 3.6 per cent. Forty-eight had come to Colorado because of asthma. This leaves sixty-six, or 2.1 per cent, with asthma of native origin. Food was given as the cause of asthma by 39 per cent, pollen by 21 per cent, bacteria or infection by 11 per cent and dust or epidermals by 7 per cent; for the remaining 22 per cent the cause was not definitely known. All the subjects had sought medical diagnosis and treatment, although less than 30 per cent had received specific allergic diagnosis and treatment. In table 2 and chart 2 their cases are summarized as to the age at onset and the duration.

TABLE 2.—*Distribution of Asthma*

Age, Years	No of Cases	Per Cent	Average Age at Onset, Years	Average Duration, Years	Per Cent Duration
0-10 ..	32	28 0	4 6	17 6	43 0
10-20 .	24	21.2	12 9	19 2	31 6
20 30	27	23 7	22 4	15 4	15 0
30-40 .	19	16 7	33.2	11 4	4 4
40-50	7	6 1	44 0	15 7	2.5
50 60	3	2 6	52 7	14 3	2 5
60 70	2	1 7	67 1	7 0	1 0

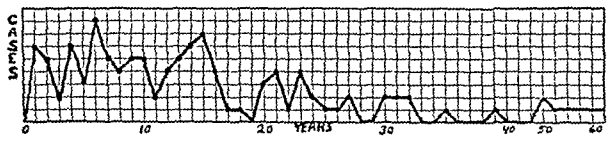

Chart 2.—Duration of asthma.

An analysis of the asthmatic group reveals that asthma is most prone to develop in the first three decades, over 80 per cent of the subjects having had it before the thirtieth year. The average duration is a little higher in the asthmatic group than in the hay fever group. There is a decline in the duration of the disease in each decade. Fifty-one per cent of the subjects were males and 49 per cent females.

Migraine.—One hundred and sixteen persons had migraine considered to be allergic in origin. In this group it was necessary to exercise considerable care in selecting the cases. Approximately 15 per cent of the subjects had been observed in the office. The remaining 85 per cent either had other allergic manifestations or presented a strong family history of migraine. Seventy-one per cent were aware that specific foods would either precipitate or aggravate an attack, although the known specific substances were not entirely responsible for the symptoms. The remaining 29 per cent were convinced that food was a factor in causing their migraine. These 116 subjects represent approximately 3 7 per cent of the general population. Twenty-one, or 0.7 per cent, had migraine before coming to Colorado, so that 3 per cent had acquired an allergy in residence. Their cases are summarized in table 3 and chart 3 according to age and the duration of the condition.

The figures indicate that migraine is most prone to develop in the second, third and fourth decades. The average duration of this condition was found to be considerably longer in persons in whom it developed between the ages of 10 and 20, although 43 per cent of the subjects were found to have had it for less than ten years and approximately 75 per cent for less than twenty years. Of the subjects 68 per cent were females and 32 per cent males.

Eczema.—Ninety-one persons had eczema of allergic origin, an incidence of 2.9 per cent in the population at large. Twelve had eczema before coming to Colorado, so that the incidence of eczema of native origin was 2.5 per cent. Food was either known or considered to be a factor with all but seven for whom pollen was found to be the cause. Twenty-two per cent had been studied from an allergic standpoint, with adequate food tests, and practically all were children under 5 years of age. Forty-one per cent were males and 59 per cent females. A large percentage had received local treatment, either by a dermatologist or under the direction of their own physician, and usually the history revealed that the patient improved under local treatment for a time, only to suffer an exacerbation as soon as it was discontinued. Older subjects frequently gave a history of childhood eczema. Eczema was frequently associated with other allergic conditions. The ages at onset and the duration are reported in table 4 and chart 4.

TABLE 3.—*Distribution of Migraine*

Age, Years	No. of Cases	Per Cent	Average Age at Onset, Years	Average Duration, Years	Per Cent Duration
0-10..	8	7.0	7.7	13.1	48.3
10-20.	32	27.6	14.2	22.0	25.0
20-30 .	27	23.3	22.8	14.8	16.1
30-40..	33	28.4	34.2	9.0	4.3
40-50..	12	10.3	46.2	8.7	4.3
50-60.	4	3.4	51.2	12.0	....

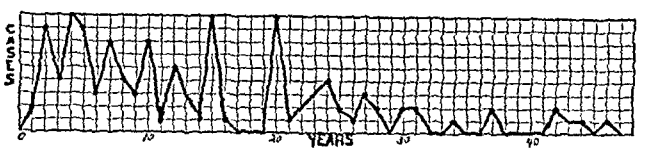

Chart 3.—Duration of migraine

In 56 per cent of the subjects eczema had developed in childhood, and in 71 per cent it had had a duration of less than ten years. There is a progressive decline in each decade in the percentage of patients acquiring eczema. The average duration of eczema in every age group except one was less than ten years. However, in going over the individual histories it was found that the duration varied from a few months to forty-one years. This group of subjects, I feel, represents the minimum number of persons with eczema of allergic origin in the general population.

TABLE 4.—*Distribution of Eczema*

Age, Years	No. of Cases	Per Cent	Average Age at Onset, Years	Average Duration, Years	Per Cent Duration
0-10.	51	56.0	3.8	9.9	71.5

40-50.	5	5.5	45.6	6.6	1.1
50-60	4	4.4	52.5	7.5	.

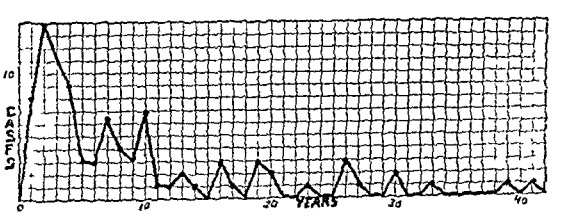

Chart 4.—Duration of eczema

Urticaria.—The fifth group is composed of patients presenting either urticaria or angioneurotic edema. None with minor allergy are included. It was very striking the number of times that urticaria was encountered as a minor allergy. Almost 100 per cent of the persons having urticaria as a major allergy were aware of specific foods that would produce their symptoms, so that almost all those with major allergies also suffered from minor allergies. This group is composed of 103 subjects, the incidence thus being 3.2 per cent in the general population. Of these, 2.5 per cent had urticaria of native origin and 0.7 per cent had had their symptoms before coming to Colorado. Their cases are summarized in table 5 and chart 5.

Almost 50 per cent of the subjects had acquired urticaria in the first decade, and the average duration of the condition was under six years. These children did not have just an occasional rash; the attacks would usually last several weeks, and in the intervals between exacerbations as a rule they would not be completely free. Approximately 20 per cent had received allergic diagnosis and treatment. Food was listed as the predominating cause in every case. In ninety-two cases it was given as the only factor involved; in three cases epidermals and foods were blamed, and in eight the cause was listed as unknown although the patient suspected that food was a factor. Sixty-two per cent of the group were females and 38 per cent males.

TABLE 5.—*Distribution of Urticaria*

Age, Years	No. of Cases	Per Cent	Average Age at Onset, Years	Average Duration, Years	Per Cent Duration
0-10.	48	46.6	5.2	6.6	67.9
10-20	28	27.2	14.3	15.0	19.5
20-30	12	11.6	24.2	12.7	9.7
30-40.	11	10.6	33.0	10.3	2.9
40-50 . . .	4	4.0	45.5	14.2	
50-60 . . .		. .	.		

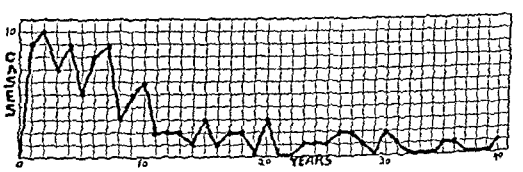

Chart 5.—Duration of urticaria

Gastrointestinal Allergy.—Without exception food was given as the cause of this condition. None of the persons in whom inhalants were found to cause symptoms are included, although a few were encountered among the persons with hay fever. All the subjects could name one or more foods that would precipitate the symptoms, but the elimination of the known substances was not sufficient to relieve the condition. With children in the first decade, the parents were able to eliminate one or more foods from the diet because symptoms would follow their ingestion. This group is composed of 106 persons, the incidence in the general population thus being 3.3 per cent. Their cases are summarized in table 6 and chart 6.

Heredity.—The influence of heredity in allergic diseases has been the subject of investigation by a great many writers. The tendency to become hypersensitive

may be transmitted from the mother, from the father or from both parents. In this survey it was found that a history of major allergy in the first degree (father, mother, brother, sister) was obtained in 16.2 per cent of the cases from the maternal side, in 10.3 per cent of the cases from the paternal side and in 4.6 per cent of the cases from both sides. This gives a total incidence of the inheritance factor of 35.7 per cent. If the inheritance was transmitted from parent to child as a dominant mendelian characteristic, one would expect to find an inheritance factor of 50 per cent in the case of unilateral inheritance and of 75 per cent in the case of bilateral inheritance. If a comprehensive survey was to be made which would include the history of both major and minor allergy as inheritance factors, I feel certain that a factor considerably higher than 35.7 per cent would be obtained for the parents. An analysis of the 2,430 nonallergic persons showed an allergic heredity for 9.3 per cent.

COMMENT

This survey indicates that major allergy is manifested by over one fifth of the general population, and, if one combines this result with the results of Vaughan [9] and Pipes [10] on the occurrence of minor allergy, it is evident that at least three fourths of the population manifest allergy to a greater or lesser degree. Allergy then, as has been pointed out, is no longer the exception but the rule.

It will be noted that in this series the duration of allergy in each of the age groups was usually between ten and fourteen years. The duration was considerably less in cases of adequate diagnosis and treatment than in those of inadequate treatment.

In the cases of food allergy the frequency with which the elimination diet had been used was noted. Some of the patients could alleviate their symptoms by its use but as a rule it was ineffective in greatly relieving the condition. The fact that persons with major allergies

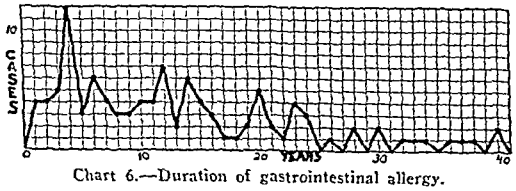

Chart 6.—Duration of gastrointestinal allergy.

are usually sensitized to a number of foods and do not manifest an immediate reaction argues against the effectiveness and reliability of the elimination diet in major allergy.

This survey revealed that 35.7 per cent of the allergic subjects had a family history of major allergy, while of the nonallergic subjects only 9.3 per cent had such a history. Vaughan [9] has hypothesized that the natural tendency of allergy is toward recovery, toward a gradual loss of sensitization. Perhaps this will be borne out by future reports; however, present reports indicate that major allergy is becoming more frequent in the general population. The various allergies when classified by age groups appear to have a limitation as to duration, and certainly with treatment the tendency is toward recovery.

CONCLUSIONS

1. A survey of the city of Colorado Springs reveals that 22.6 per cent of the general population have one or more major allergic manifestations.

2. The incidence of hay fever was 10.06 per cent, of asthma 3.6 per cent, of eczema 2.9 per cent, of migraine 3.7 per cent, of urticaria 3.2 per cent and of gastrointestinal allergy 3.3 per cent.

3. A positive family history of major allergy was obtained for 35.7 per cent of the subjects with major allergy and for 9.3 per cent of the nonallergic subjects.

4. Approximately 16 per cent of the allergic persons presented more than one major allergic manifestation.

THE LEVER AT THE TOP OF THE FEMUR AND ITS SURGICAL ELONGATION

FRED H. ALBEE, M.D., Sc.D., LL.D.
NEW YORK AND VENICE, FLA.

If one were to inquire of the average practitioner the function of the olecranon process at the elbow, I am certain one would in a large percentage of instances receive essentially the correct answer, namely that active extension of the elbow joint is produced from the pull of the triceps muscle on this lever acting purely as a lever. I feel that there would be little confusion as to the importance of the leverage of the olecranon process in the movements of the elbow and arm. The influence of function on the lever at the top of the femur (head-neck-great trochanter) is of equal importance and identical in mechanical principle with that of the olecranon process, and yet few practitioners specializing in surgery of the joints have appreciated the importance of this action and its tremendous influence on the structure and function of the hip joint; at least no suggestions have ever been made to *modify its length* surgically when the necessity was evident.

In a newly surgically made hip joint a postoperative dislocation may occur because of the inadequate length of this lever. The pelvis may tip upward or the femur pull inward in adduction, with varying resultant practical shortening of the limb, or weight-bearing weakness with marked limp. Such limp has often been mistaken for that of shortening of the limb, and many patients have been brought to me with a request that the limb be lengthened when there was little or no actual bony shortening.

The contrast in favor of the importance of the lever at the top of the femur is even greater, in that the olecranon process functions only to enable active extension whereas the lever at the top of the femur not only is the essential element in providing a mechanism for abduction and inward and outward rotation of the lower limb at the hip but is essential to the stabilization of the

From the Florida Medical Center.

hip joint and the active control of the weight-bearing relation between the femur and the pelvis. One muscle is inserted into the olecranon process and seven are inserted into the outer end of the lever at the top of the femur, namely the gluteus medius, gluteus minimus, obturator externus, piriformis, gemellus superior, obturator internus and gemellus inferior.

With the sole exception of adduction, all movements at the tip have to do to a greater or less degree with the pull of certain muscles on the outer end of this lever.

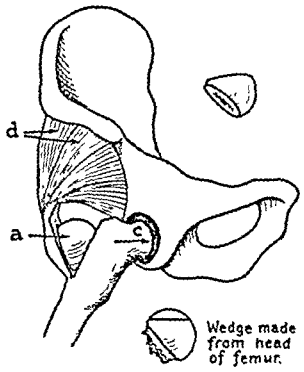

Fig. 1.—Method of elongating the lever at the top of the femur in cases of ununited fracture of the neck of the femur in which much absorption of bone has occurred because of an inadequate blood supply. The removed femoral head is transformed into a wedge and placed at *a*. It serves three purposes: (1) it holds the newly formed head firmly in the acetabulum at *c* and prevents dislocation; (2) it restores active weight bearing, and (3) it restores abduction by providing a longer lever for the gluteal muscles (*d*) to pull on.

In industry or in everyday life, if the force available to be directed on the end of a lever is inadequate and it cannot be increased, the only recourse is to elongate the lever so that the same available force will be adequate to the lifting of the corner of a building or a rock. This principle I have applied in the case of both the olecranon process and the lever at the top of the femur. That is, I have lengthened these structures to the anatomic dimension when they have been shortened by disease, by trauma or by inadequate development. In such instances it is assumed that the muscular force is physiologically normal. On the other hand, when the muscular forces which normally activate these levers have been weakened from any cause whatever, particularly infantile paralysis, it follows by the same token that the elongation of these lever structures beyond their anatomic normal dimension is equally indicated. The results obtained by such surgical procedures have been most gratifying. This principle was first applied by me over twenty years ago to ununited fractures of the neck of the femur with extensive absorption of bone in my so-called reconstruction operation (fig. 1).

A shell of bone about 3½ inches long obtained from the superior and outer surface of the great trochanter is turned outward with the muscle insertions undisturbed, and into the crotch thus made fragmented grafts are packed, the purpose being to afford a longer lever for these muscles to pull on, thus preventing postoperative dislocation and restoring abduction and active weight bearing.

Other conditions for which this technic has been applied are shortening of the neck of the femur from destructive lesions such as tuberculosis, when the disease has been cured, leaving marked shortening of the neck of the femur, and old reduced congenital dislocation of the hip with the same result. In many cases there have been marked adduction deformities with resultant practical shortening, and particularly in the case of the healed tuberculous hip the teaching has been in the past either to correct the adduction by Gant's osteotomy or to correct it at the hip joint, with a supplementary fusion operation. In most instances the latter destructive operation, with loss of motion, was found necessary because repeatedly the adduction would slowly recur. The reasons why this was so have not been explained. The outstanding feature of these cases has been the shortening of the lever at the top of the femur. The adductor muscles function with their normal mechanical advantage at the same time that their antagonistic muscles are markedly handicapped in that they are pulling on a bony lever which may be less than one half its anatomic length. Is it surprising, under these conditions, that the correction of an adduction deformity by osteotomy at the lesser trochanter should recur? The indications as I see them now in such cases are to correct the deformity and then restore the abductor bone lever to its normal dimension or even to greater length. With some of these conditions, either of congenital or of pathologic origin, there has remained a bone block at the superior periphery of the hip joint which had to be removed when the lever was lengthened in order to allow freedom of motion of the hip joint.

Another important indication for surgical reconstruction occurs in cases of arthroplasty to restore motion to a bony stiff hip joint when this lever has been shortened both by the destructive lesion which produced the ankylosis and by the necessary removal of bone by the surgeon in modeling the new joint. In this instance, in the discretion of the surgeon, the lever may be lengthened at the primary arthroplastic operation to restore motion, or this procedure may be deferred to a later date. In borderline cases in which there is doubt as to whether the lever is sufficiently long it is urged that the secondary procedure be deferred until the defective function of the joint proves this necessity.

My last application of this kinesiologic principle has been demonstrated in cases of infantile paralysis in which there has been a weakening of the group of muscles attached to the tip and outside of the great trochanter. In this instance one would immediately reason that the lever is of normal physiologic length, but this has not been found to be the case at all. The weakening of the trochanter muscles has resulted, as one might expect, in the general lack of development of the whole upper end of the femur, and this has caused a diminution in the longitudinal dimensions of this lever. Therefore the indications for its elongation are double; namely, the muscular force which activates it has been lessened below functional capacity, and at the same time the lever has become shortened. The surgical results from reconstructing this lever, as might be anticipated, have in many cases been brilliant.

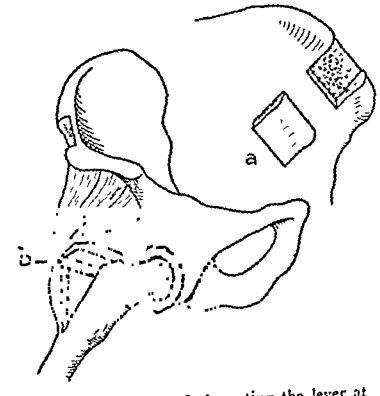

Fig. 2.—Method of elongating the lever at the top of the femur in cases of weakness of the abductor or weight-bearing muscles, whether from infantile paralysis or other cause. A rectangular graft is obtained from the outer crest of the ilium, including as much of the outer table of the ilium as is found desirable (*a*). This is placed at *b* and firmly holds the bony structures in the elongated position. Care should be taken in freeing the top and outer portion of the great trochanter not to sever or unnecessarily damage any of the short trochanteric muscles.

TECHNIC

1. For many years following the introduction of my reconstruction operation of the neck of the femur, described in 1919, I have devoted myself intensively to

the development of the simplest surgical technic for all occasions in lengthening this lever. The availability of bone graft material is almost a determining element in the design of the special technic. The object is to have a massive graft which not only will serve eventually to fuse in place and reconstruct the lever but will immediately elongate the lever by its mass support. In the instance of ununited fracture of the neck of the femur, the removed head of the femur serves this purpose admirably. Formerly I always threw this away and used numerous small fragmented bone grafts, but during the past ten years or more I have been able to shape it quickly into the form of a wedge, using a motor saw and osteotome for this purpose. This massive wedge, when properly placed, immediately supports the lever in its elongated state and serves forthwith to prevent the dislocation of the newly formed femoral head from the acetabulum. Because of its extensive mass, it allows ample leeway in shaping a wedge of the desired size, and only three weeks of postoperative immobilization has been necessary. Because of this, free motion of the joint is much more easily restored. When fragmented grafts were used, it was even necessary to immobilize by double plaster of paris spica cast for a long period, at least eight weeks, in order to allow time for the grafts to unite firmly and consolidate the new lever, so that postoperative dislocation of the newly made hip joint would not occur (fig. 1).

2. In cases of shortening of the neck of the femur from ancient cured disease, from congenital malformation or from former arthroplasty in which this lever has been shortened, both by the destructive lesion that produced the osseous tuberculosis and by the removal of bone by the surgeon made necessary in modeling a new joint, the bone graft material can be obtained from the side of the ilium, always high up at the crest so as not to disturb either the muscular structure or its elevation. It can also be obtained from the anterior internal surface of the tibia, the most satisfactory store house of bone graft material. At the discretion of the surgeon this lever may be elongated during the primary operation to produce motion in a bony stiff joint. In this instance the side of the ilium has been already laid bare and therefore the material for the elongation of the lever can be easily obtained.

Formerly I obtained the grafts from the side and crest of the ilium in the form of two "pieces of pie" (segments of a circle) consisting of the outer half of the crest and the outer iliac table, of proper shape and size to fill in the bony wedge cavity which is produced by the turning out of the shell bone from the tip and side of the great trochanter. These may be fastened together with a bone graft peg.

The technic, however, which I employ at present is to obtain the graft in the shape of a square or a rectangle from the outer table of the ilium, including the outer half of the crest. This is placed in accordance with and immediately supports firmly the lever in the elongated state (fig. 2).

The technic in cases of infantile paralysis is precisely the same. However, one caution should be firmly adhered to; that is, if the graft is obtained from the outer surface of the ilium it should be from the extreme upper anterior border, including a portion of the crest, so that the weakened muscles will not be disturbed more than is absolutely necessary.

Clinical Notes, Suggestions and New Instruments

AN IMPROVED METHOD OF APPLYING MOIST HEAT TO INFECTED EXTREMITIES

J. R. COCHRAN JR., M.D., CHICAGO

It is customary in the treatment of infections of the extremities to utilize the beneficial effects of moist heat. The routine at St. Luke's Hospital has consisted in wrapping the arm or leg in double folded blankets which have been heated in the steam sterilizer, encasing them with a sheet of oiled silk and wrapping both with a bath towel. The blanket is applied at the highest temperature that the patient can tolerate and is allowed to remain for two hours. Thus in the application of continuous moist heat the fomentations are changed by the nurses from eight to twelve times a day.

For several reasons this method, which is not unlike that used in many other hospitals, is inconvenient and unpractical and, as will be shown, fails to maintain an atmosphere of moist heat for more than a fraction of the total time applied. More specifically, it is next to impossible for the nursing staff to maintain the two hour schedule of changing the foments on the busy surgical floors. It is also common to find the bedding around the foment soaked after several changes, owing to the fact that the oiled silk becomes cracked with use and also because of the haphazard method of wrapping. In practice it was observed that the constant changing of the fomentations defeated the attempts at immobilization of the infected extremity, a factor considered most important in the therapy of infections. But most important of all the objections was that voiced by numerous patients, particularly by members of the staff who at various times have been under treatment for infected hands; namely, that the foments failed to keep the part warm for the duration of the application.

To test the validity of some of these observations, temperature recordings were taken on a group of patients by placing a mercury bulb thermometer in the fomentations in such a way as to record the mean temperature of the foment layers. In an attempt to evaluate the results, an arbitrary base line of 100 F. was selected, this temperature being several degrees above the average temperature of the skin and therefore suitable for elevating the temperature of the cutaneous layers and also low enough to obviate burns. The results of our readings have indicated that the routine being used failed to maintain the temperature above the base line for more than from 10 to 15 per cent of the two hour period and that in twenty-four hours of continuous therapy the infected area was actually heated about three hours. At the end of one hour the temperature averaged 93 F., and at the end of two hours 90 F.

An alternative method occasionally used here was then tested out. This consisted in placing a light cradle or electric baker over the fomentations. Readings on a series of four patients receiving repeated fomentations showed that with two 60 watt bulbs the temperature never reached the base line, while with three 60 watt bulbs the temperature could be raised to 100 and no further. Likewise, during each two hour period approximately 25 per cent of the heating effect was lost while the nurse changed the blankets with the cradle removed. The patients complained of aching of the part during the latter part of each treatment when the blanket had dried.

It was then decided that the latter method might be improved by applying the fomentations in a different manner designed to obviate the objections outlined. After several trials the following method was adopted:

The extremity is first covered with petrolatum or preferably with the antiseptic oil used in the nursery. This serves to prevent excess damage of tissue and to hinder the seeding of infection to adjacent hair follicles. The extremity is then wrapped completely around twice with double thickness hot foment blankets. Into the more superior portion of the blankets

are incorporated two rubber tubes perforated at intervals of about 1 inch. These tubes are connected to a 2 foot tube by a Y connection, and the single tube is attached to a funnel strapped to the light cradle. The extremity is arranged so that the proximal part of the tube is higher. The spacing of the perforations and the inclination of the tube serve to distribute the water evenly throughout the foment. Two thicknesses of oiled silk are then wrapped round the blanket and the edges turned on themselves and clipped with large spring paper clips. The ends are carefully folded in to make it water-tight. By means of careful wrapping the bed can be kept dry and comfortable all day. A light cradle is then put over the extremity and covered with a blanket to insulate it against loss of heat.

Temperature recordings taken in more than twenty cases indicate that it is possible to maintain a temperature slightly over 100 F. over long periods of time with one 60 watt bulb. With two 60 watt bulbs temperatures went as high as 112 F. It is inadvisable to use more than 100 watts of energy for fear of burning the patient.

In practice the majority of patients are allowed to moisten their own fomentations as they see fit. Otherwise the nurses pour between 30 and 50 cc. of water into the funnel every hour. The foments are changed only as desired for inspection of the infected area. The extremity is therefore immobilized for long periods.

St. Luke's Hospital.

A CASE OF LEAD ENCEPHALOPATHY IN A BREAST-FED INFANT DUE TO THE USE OF LEAD NIPPLE SHIELDS BY THE MOTHER

MILTON RAPOPORT, M.D., PHILADELPHIA, AND ATHOL S. KENNEY, M.D., NEW ORLEANS

Since the report by Wilcox and Caffey in 1926 [1] of two cases of lead poisoning in nursing infants due to the use of lead nipple shields by the mothers, the potential danger of these devices as a source of plumbism in the nursing infant has been noted. Although lead poisoning is being recognized with increasing frequency in infancy, being due to the ingestion of paint, the use of lead-containing cosmetics by the nursing mothers (Japan), the burning of storage battery boxes and the like, we have found no cases reported attributable to nipple shields since the report of Wilcox and Caffey.

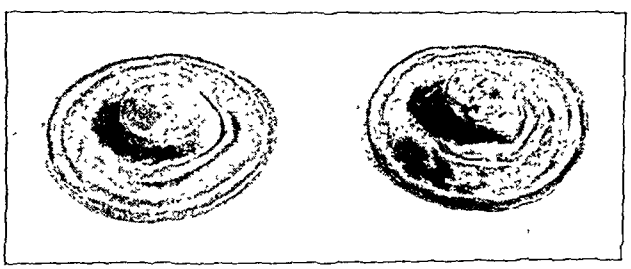

Fig. 1.—Lead nipple shields used by mother of patient.

However, when one considers the fact that the lead nipple shield must be in fairly common use, since it is recommended as a remedy for fissured nipples by many of the standard textbooks of obstetrics,[2] it is quite possible that there are unrecognized cases of lead poisoning in infants due to the use of such shields.

It is interesting to note that the harmlessness of the lead nipple shield to the infant is stressed in the circular found in the container of the lead nipple shields sold in this country. This circular read as follows:

Dr. Wansbrough's
CELEBRATED
Metallic Shields
For the Prevention and Cure of SORE NIPPLES

Highly recommended by Dr. Laycock and the most eminent medical men throughout the United Kingdom

The merit of the invention is now so fully understood, and the good results from its application so well established by the experience, both of the Medical Profession, and of numerous Mothers who have been afflicted with Sore Nipples, that the Manufacturer feels he is doing a duty to society by giving as much publicity as possible to a discovery which has proved so great a blessing in these distressing cases.

The attention of the Medical Profession was first drawn to this subject by DR. WANSBROUGH (the inventor), in a paper published in the *Lancet*, July, 1842; and he afterward brought it before the Society of Arts, in 1843, when he read a paper to that Society entering fully into the nature of the above malady, and the philosophy of this instrument, both as a preventive and a cure.

The following is an extract from the above Paper, which he then delivered and which is published in their transactions:

"Among all the various remedial means that have been proposed for *this painfully distressing affection, none have hitherto proved sufficiently* effectual, either as a preventive or cure. The subject has occupied the attention of Medical Men for a considerable period, and numerous have been the remedies recommended and applied; but they have failed in the desired result. Now, Gentlemen, *this little Apparatus which I have the honor to submit to your notice possesses these great desiderata.* As a preventive, it is requisite only to say, that it effectually accomplishes the desired end by being applied immediately after delivery. Its curative character consists *in the nipple being immersed in a solution of Lactate of Lead, formed by the Lactic Acid in the milk acting upon the metal;* the whole contained in a reservoir, as it were, in the cavity of the Shield, which prevents pressure, and by adhering closely, may be worn with the dress. I have used these Sheilds in the most severe cases, in a somewhat extensive practice, for upwards of a quarter of a century, *even where the Nipple has suppurated and sloughed to the extent of half its volume, threatening the destruction of the whole,* AND I HAVE NEVER EXPERIENCED A FAILURE! Yes, Gentlemen, this little, apparently trifling, and intrinsically valueless article, because formed of a material in the lowest scale of metallurgy, possesses, nevertheless, most powerful properties when put to the proof."

DIRECTIONS

For the prevention and cure of Sore Nipples, these Shields *should be applied as soon after delivery as possible, and in using them the only* attention required is to wipe the Nipple previously to nursing, and apply *the Shield again immediately afterwards. They are in no way likely to be injurious to the infant.*

Should the edge of the Shield become inverted, it may be instantly restored by being laid on a flat surface, and rubbed round with the finger.

In this report we are presenting the case of a 3½ months old breast-fed infant in whom a severe lead encephalopathy developed as a result of the use of lead nipple shields by his mother.

History.—N. V., a white male infant, aged 3½ months, was admitted to the wards of the Children's Hospital Dec. 19, 1936, with a provisional diagnosis of meningitis.

The family history was inconsequential, the patient being the only offspring of young and healthy Italian parents. He was born in a Philadelphia hospital after an uneventful full term pregnancy and normal labor. The birth weight was 7 pounds 13 ounces (3,545 Gm.).

The past history showed a normal gain of weight until the onset of the illness leading to admission. About one month prior to admission a mild infection of the upper respiratory tract developed, which subsided within a few days. Feeding presented no difficulty, the child having been fed solely on breast feedings every three hours. Orange juice and cod liver oil supplements were added at the age of 1 month and continued in adequate amounts.

The illness leading to admission to the hospital began abruptly on the afternoon of the day prior to entry, being ushered in by projectile vomiting. The vomiting recurred several times that day, and the following morning generalized clonic convulsions developed. He was seen twice that day by a physician, who prescribed for an "upset stomach" and ordered the infant to have two enemas and a mustard bath. His condition remained unchanged, the clonic convulsive seizures recurring at frequent intervals, and between the convulsive episodes he remained tonic and unconscious. He was seen that evening by one of us (M. R.) and a tentative diagnosis of meningitis was made. Following the visit he was referred to the hospital for admission.

From the Department of Pediatrics, University of Pennsylvania School of Medicine, and the Children's Hospital of Philadelphia.

2. De Lee, J. B.: The Principles and Practice of Obstetrics, ed. 6, Philadelphia, W. B. Saunders Company, 1933, chapter 67, p. 964. Edgar, J. C.: Practice of Obstetrics, ed. 6, Philadelphia, P. Blakiston's Son & Co., 1926, part VII, p. 528. Schumann, E. A.: A Textbook of Obstetrics, Philadelphia, W. B. Saunders Company, 1936, chapter 39, p. 633.

Physical Examination.—The temperature was 97.8 F., respirations ranged between 48 and 60 and the heart rate was 120.

The patient was well developed and well nourished and weighed 12 pounds 3½ ounces (5,543 Gm.). His length was 55 cm. and the circumferences of his head, chest and abdomen were 40, 41, and 43 cm. respectively. At the time of the examination he was undergoing a generalized clonic convulsive seizure of moderate severity. Breathing was rapid and stertorous. The skin was pale and the extremities were cold and clammy.

The contour of the head was normal. The anterior fontanel was patent and tense but not bulging. There was no retraction of the head, and no definite nuchal rigidity was present. Tonic reflexes of the neck were elicited.

Pandy's reagent showed a moderate increase in globulin; the cell count totaled 5 per cubic millimeter—all lymphocytes. A stained smear and later culture both proved to be negative. Another tap done five days later showed exactly the same changes.

Because of our failure to detect any evidences of infection, and because of the increased amount of globulin in the spinal fluid, lead poisoning was suspected. The mother was recalled the following morning for further questioning as to a possible source of the ingestion of lead. She stated that during the puerperium her nipples had cracked and on leaving the hospital she had been advised to use lead nipple shields. Her husband had obtained these after a prolonged search among at least a dozen drugstores. They were worn constantly between nursings, the nipples being cleansed with boric acid solution before and after each feeding.

The pupils were equal in size and were dilated. They responded sluggishly to light. A rapid horizontal nystagmus was present, with the quick component to the left. Opthalmoscopic examination revealed normal fundi.

The ears and ear drums were entirely normal. The nose was normal. The mouth was firmly closed and could be opened only with force. No teeth were present. The tongue, mucous membranes, tonsils and pharynx were entirely normal.

The chest was symmetrical and the heart and lungs were normal.

The abdomen was moderately distended; the liver edge was palpable 1.5 cm. below the right costal margin, and the spleen 2 cm. below the left costal margin. The kidneys were not palpable.

The arms were flexed and rigid; the hands were tightly clenched. The legs were extended and rigid. A right talipes equinus was present which had first been noted at birth.

The tendon reflexes (achilles, patellar, biceps and triceps) as well as the abdominal reflexes were hyperactive. A marked ankle clonus was elicited on the right. The Kernig sign was present in both lower extremities.

Immediately following examination a lumbar puncture was done. The pressure was found to read 18 mm. of mercury;

Routine examination showed an erythrocyte count of 3,000,000; the leukocyte count was 21,000 and the hemoglobin content 55 per cent (Sahli). Considerable coarse basophilic stippling of the red cells was found in the smear. X-ray examination showed wide dense zones of temporary calcification in all the long bones (fig. 2).

In view of the established source of the ingestion of lead, and the hematologic and radiologic changes, a definite diagnosis of lead encephalopathy was made.

Treatment and Progress.—The convulsions were controlled by the rectal administration of 2½ grains (0.16 Gm.) each of sodium bromide and chloral hydrate every six hours. In addition one-half grain (0.032 Gm.) doses of sodium phenobarbital were given hypodermically twice a day. By the second hospital day the convulsions and vomiting had ceased entirely. However, the infant continued to be hypertonic and showed a generalized hyperreflexia. At this time diarrhea developed and he passed about four loose greenish stools daily. This was treated by dietary means, a dilute skim milk mixture being fed to which had been added 5 per cent rice flour. The diarrhea

subsided after three days. During the interval the administration of sedatives was continued.

At this time there was a recurrence of the convulsive seizures, and evidence of a nasopharyngitis was found. A second lumbar puncture was done, revealing a similar amount of globulin. It

ducing a mobilization of lead from the bones and increasing the amount in the general circulation.

Measures were now employed in an attempt to deposit the circulating lead in the bones. To this end, 40 grains (2.6 Gm.) of disodium phosphate and 20 drops of viosterol were given daily in divided doses. In addition two blood transfusions of 60 and 90 cc. were given on successive days to correct the anemia. Twenty-four hours after the institution of this therapy the convulsions had ceased and did not recur for the remainder of the infant's stay in the hospital. The disodium phosphate was discontinued after fifteen days. The viosterol was continued during the entire hospital stay. An acute suppurative bilateral otitis media, which developed on the twelfth day and which required a bilateral myringotomy, produced no exacerbation of his symptoms, the ears healing uneventfully after a period of three weeks.

In the accompanying table are summarized the results of examination of the infant's blood during his stay in the hospital. The numerous reticulocyte counts and counts of stippled cells were made to determine whether there was any relationship between the two (fig. 3). During the height of acute symptoms when the hemoglobin was low and there were fairly numerous reticulocytes, there were numerous cells showing basophilic stippling. When the hemoglobin had been raised to 86 per cent the number of reticulocytes declined and no stippled cells were seen. As the number of reticulocytes increased, presumably in response to a fall in hemoglobin, stippled cells were again seen. Even though the number of reticulocytes continued to be increased, the stippled cells disappeared from the blood. This last event was interpreted as an indication that lead had been driven from the blood stream and deposited in the bones, so that it could not produce basophilic stippling. This sequence of quantitative changes in reticulocytes, stippled cells and anemia is graphically shown in figure 3.

The inference that was drawn from these blood studies was that in the presence of lead circulating in the blood stream there was an apparent direct correlation between the number of reticulocytes and the number of stippled cells.

The infant remained in the hospital for a total period of eleven weeks and on discharge appeared to be in good condition. His weight at that time was 16 pounds 2 ounces (7,314 Gm.). He was active and happy, could sit with a little support and reacted normally to his environment. Both liver and spleen remained palpable to the same extent as on admission.

Fig. 4.—Patient at 22 months of age, June 1938.

Following his discharge from the hospital, the infant continued to grow and develop in normal fashion. On reexamination at 11 months of age the infant was very well nourished and well developed, weighing 22¾ pounds (10.3 Kg.). He was 29 inches (73.7 cm.) tall, had four teeth and was able to walk by himself. He had mumps at 8 months, measles at 10 months and whooping cough at 14 months, from all of which he recovered uneventfully.

In June 1938 at 22 months of age he was entirely normal physically and mentally (figure 4). Roentgenograms taken at this time showed that the vestiges of old lead lines were still visible (figure 5). At no time following his discharge from the hospital did he manifest any symptoms or stigmas which could be attributed to his lead poisoning.

SUMMARY

1. A case of lead encephalopathy in a 3½ months old breast-fed infant in which there was complete recovery, was caused by the use of lead nipple shields by the mother.

2. There is an apparent correlation between the number of reticulocytes and the number of cells showing basophilic stippling.

Special Article

DIPHTHERIA MORTALITY IN LARGE CITIES OF THE UNITED STATES IN 1938

SIXTEENTH ANNUAL REPORT

The means employed for obtaining the data for this review have been outlined in the report on typhoid deaths.[1] As has been the practice in all previous annual reviews of diphtheria and typhoid, statistics have been obtained from local health officers. As the time of the 1940 census approaches, local estimates of population become less trustworthy. They provide, however, the best available data. The rates must be readjusted in light of the facts obtained at the time of the next federal census.

As has been the case in previous articles, the local health departments report not only the total number of diphtheria deaths that actually occur in the community but also the number of such deaths occurring among nonresidents.

The fourteen New England cities (table 1) report a continued downward trend in the death rate for the twenty-one in 1937 to seventeen in 1938 (table 16). The death rate fell from 0.79 to 0.64. In 1937, of the nine cities with the highest diphtheria death rate, two were in the New England group. In 1938 none are in this group.

The eighteen cities in the Middle Atlantic states (table 2) continue to hold first place. The group rate of 0.48 is significantly lower than that of 1937 (0.71)

group as a whole but have been unable to approach the record of the Middle Atlantic cities, which continue to hold first place (table 16). While there were eight cities in the New England group which recorded no deaths in 1937, there were only six such cities in 1938 (Springfield, Lynn, Lowell, New Bedford, Providence, New Haven). There has occurred no death among residents in Springfield and New Haven during the past four years; none in Lynn, Lowell and Providence during the past two years. No death from diphtheria or typhoid has occurred in Lynn in two years. Lowell, New Bedford and Providence report no death from either diphtheria or typhoid in 1938. Four years has passed without a death among residents from diphtheria or typhoid in Springfield. Boston and Hartford each report two diphtheria deaths, all in nonresidents. The excellent records in Cambridge and Somerville were marred by one death among residents in each city. The total number of deaths in the area decreased from

° Corrected rate. In review for 1936, Yonkers reported cases instead of deaths.

and 1936 (0.65). The new rate represents a new all-time low. In 1937 there were ninety-five deaths, in 1938 but sixty-four. This group of cities, which reported the lowest quinquennial average for 1930-1934 (2.50), has maintained the lowest group rate for the past four years. There are two cities in this group with a rate above 2.0 (Camden, Reading). Eight cities (Rochester, Utica, Erie, Elizabeth, Syracuse, Albany, Yonkers, Paterson) appear in the select list (table 11) with no diphtheria death in 1938. Utica reports no death in five years; Rochester and Erie report none in four years; Elizabeth reports none in three years. Utica records no diphtheria or typhoid death in three

patients who died, one was 14 years of age, two were 11, one was 9 and one was 6. A rechecking of the protection status of school children has been instituted.

The nine cities in the South Atlantic states (table 3) report forty-three deaths in 1938, in contrast to fifty-three in 1937 and sixty-seven in 1936 (table 16). The death rate has fallen from a quinquennial average of 3.54 for 1930-1934 to 1.63 in 1938. There is no city in the area without a death during the past two years; Richmond, however, reports only two deaths in 1938, both among nonresidents. Of the nine cities in the group, five (six in 1937) report that one third or more of the deaths occurred among nonresidents. Atlanta remains the only city with a rate as high as 4.0. There is a total of eight such cities (table 9) and Atlanta records the lowest rate in the group of eight. It must be emphasized however that, of thirteen deaths in Atlanta, six were among nonresidents. Of six deaths

in Baltimore, three occurred among residents. During 1938 there was some modification in Baltimore of the previous program for securing protection of children against diphtheria through preventive inoculation of alum-precipitated toxoid. Diphtheria prevention clinics were established in all schools with at least one session a month and mothers were urged to bring preschool children to these clinics as well as to promote immunization among children of school age. In addition, a reply post card was enclosed in the usual literature sent to mothers of babies on their six months birthday for the convenience of the physician in reporting inoculations done in private practice. One result has been an increase in the number of such immunizations reported by physicians during 1938. There were 19,325 inoculations against diphtheria in 1938 as compared with 17,934 for 1937. Somewhat similar cooperation of family physicians has been obtained in many places throughout the country, especially in Michigan (Detroit), New York (Albany, Rochester), Connecticut (Hartford) and Indiana (Fort Wayne). Washington reports seven deaths, all in residents.

The eighteen cities in the East North Central states (table 4) report a decrease in the number of deaths from 186 in 1937 to 153 in 1938. The rate has decreased from 1.88 to 1.54 (table 16). While in 1937

† One third or more of the reported diphtheria deaths were stated to be in nonresidents.
Incomplete data.

there was no city on the honor roll, in 1938 (table 4) there were six such cities (Grand Rapids, Fort Wayne, South Bend, Youngstown, Peoria, Akron). Toledo reports two deaths, both among nonresidents. The single typhoid death in this city was also in a nonresident. Of the thirteen cities (table 12) with no diphtheria or typhoid death in 1938, five (Fort Wayne, Grand Rapids, Peoria, South Bend, Youngstown) are in the East North Central group. There are two cities (Indianapolis, Dayton) with rates in excess of 4.0. Of eighteen deaths in Indianapolis, seven were stated to be in nonresidents; of thirteen in Dayton, four were in nonresidents. Detroit reports seventeen deaths, two in nonresidents; Flint reports three deaths, two in nonresidents; Chicago reports seventy deaths, two in nonresidents. Detroit and Chicago report localized-area outbreaks in districts where the protection status was unsatisfactory. In Cincinnati the proportion of deaths among nonresidents was unusually high, ten out of fifteen deaths.

The cities in the East South Central states (table 5) report a rate of 3.25, compared with 3.16 in 1937 and

2.96 in 1936 (forty-four deaths in 1938, forty-two deaths in 1937, thirty-eight in 1936). The rate in these cities is the highest for all groups. There is no city with a rate below 1.0, and Knoxville has the highest of all rates for 1938. This is due to the fact that eight deaths among nonresidents are charged to a total of eleven. The hospital facilities in the city draw a large number of nonresidents from the surrounding area. Most of the deaths occurred among residents of Knox County, in which Knoxville is situated. Four cities in this group of six report one third or more of diphtheria deaths to be in nonresidents. Of five deaths in Memphis, two were of residents. Five of the eight deaths in Birmingham were among nonresidents. Nashville reports three among residents in a total of seven. After passing through 1937 with no resident death, Louisville records nine deaths in 1938, seven of residents.

* No diphtheria deaths in five years.
† No diphtheria deaths in four years.
‖ No diphtheria deaths in three years.

The nine cities in the West North Central states (table 6) report a continued decrease in rate (1.37 in 1936, 1.26 in 1937, 1.11 in 1938). The diphtheria deaths decreased from thirty-five in 1937 to thirty-one in 1938. Although there were four cities on the honor roll in 1937, only two (Duluth, Des Moines) remain on this list in 1938. Duluth reports no diphtheria death in three years, Des Moines none in two years. Allocations have not, however, been completed by the Iowa state health department. There is but one city in the group with a death rate in excess of 2.0. Of sixteen deaths reported in St. Louis, twelve occurred among nonresidents. In 1937 there were eleven among nonresidents in a total of twenty-seven. In 1938 three fourths of the deaths in St. Louis were in nonresidents. The influence of hospitalization policies is very evident. After two years with no death among residents, Kansas City, Mo., reports five such deaths in 1938 in addition to one death among nonresidents.

Lowell		

* No diphtheria or typhoid deaths in two years.
** No diphtheria or typhoid deaths in three years.

The eight cities in the West South Central group (table 7) have relinquished their unenviable position of having the highest group rate. The East South Central cities have succeeded to this position. The Southwestern cities have a rate of 2.69 for 1938, which compares favorably with the highest quinquennial average for 1930-1934 (6.55). The diphtheria deaths decreased from sixty-seven in 1937 to fifty-seven in 1938. There is no city without a death and but one city with a rate in excess of 4.0. El Paso recorded the highest rate for all cities in all groups in 1937. In 1938 there are three cities with higher rates. With six deaths in Dallas, two were among nonresidents. Of nineteen deaths in New Orleans, eleven were among residents.

1937	93	0	0	0	3	70	20
1938	93	0	0	0	3	66	24

The Mountain and Pacific states (table 8) report seventy-four deaths in 1938, an increase over the fifty-nine deaths recorded in 1937. The rate has increased from 1.43 to 1.75, approximately the same as for 1936 (1.78). There are two cities with no death in 1938

(Long Beach, Tacoma). There has occurred no diphtheria death among residents of Tacoma in four years; none in Salt Lake City in three years. Spokane, after remaining on the honor list for two consecutive years, reports one death among residents in 1938. The nine recorded deaths in San Francisco are among residents. It is reported that, in Los Angeles, thirteen of the thirty-two deaths occurred among nonresidents. The figures are identical with those for the preceding year. Denver reports fourteen deaths among residents, no record being kept for nonresidents.

Of the entire ninety-three cities there remain three with a rate of 5.0 and over (table 14). The number

* Lacks data for 1925 for Jacksonville and Miami

† Lacks data for South Bend

‡ Lacks data for Oklahoma City for 1925 and 1926.

For the entire group of ninety-three cities the diphtheria death rate in 1938 was 1.23, compared with a rate of 1.46 for 1937 and 1.51 for 1936. The actual number of diphtheria deaths has decreased by eighty-five (from 568 to 483).

The remarks from the various public health administrators indicate that intensive programs are being carried on in many parts of the country. The family physician is teaming up more frequently with the health department and medical society and dispensing more preventive services in his own office. The evidence at hand indicates that the protection programs so extensively maintained throughout the country are resulting in a lower death rate from diphtheria.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE AND REPORTS

HOWARD A. CARTER, Secretary

MEDICAL DIATHERMY

Medical diathermy is the therapeutic use of heat generated in the body tissues by a high frequency current which has insufficient local intensity to produce temperatures high enough to destroy the tissues or impair their vitality. Such currents are applied locally by three methods: (1) conventional long wave diathermy, contact metal electrodes being used, (2) short wave diathermy with an electric field, air-spaced or insulated electrodes being used, and (3) short wave diathermy with an electromagnetic field method, a cable being used.

In conventional or long wave diathermy the frequency of oscillation is usually from one-half million to three million cycles a second. In short wave diathermy the frequency of oscillations may be from ten million to 100 million cycles a second.

PHYSIOLOGIC EFFECTS OF LOCAL MEDICAL DIATHERMY

The effects of electric current when applied to body tissues may be thermal, chemical or mechanical, depending on the physical characteristics of the current. The fundamental reason for using high frequency currents for heating is that the body heat may be raised without injury or electrical stimulation.

With regard to short wave diathermy, there has arisen considerable controversy as to whether it produces specific effects other than that of heat. In the light of present observations, the consensus seems to be that no definite physiologic effects other than those attributable to heat have been substantiated. The physiologic effects of heat have been considered by Pemberton [1] and by Gill [2] and will not be discussed here

SHORT WAVE DIATHERMY VS. CONVENTIONAL DIATHERMY

The consensus seems to be that there is no great difference in the effects produced by short wave diathermy and conventional diathermy except that the former apparently produces deeper, more uniform heating and is more readily applied.

DOSAGE

The regulation of doses in medical diathermy is empirical. In short wave diathermy the only recognized method of measuring doses is the comfortable heat sensation of the patient's skin. The milliammeter on the high frequency apparatus does not measure the electrical energy passing through the patient. In high frequency apparatus the milliammeter indicates the amount of current passing through it but does not measure the electrical energy passing through the patient. The patient's tolerance is the most important guide for the final dose to be used. If it is suspected that the sensibility to heat may be deficient in the skin over which the electrodes are placed, it is advisable to

1. Pemberton, Ralph: Physiologic Effects of Heat, Handbook of Physical Therapy, 1939.

2. Gill, A. Bruce: Heat in Surgical and Orthopedic Conditions, Handbook of Physical Therapy, 1939.

test the skin with hot water in a test tube, using the operator's skin sensation as a control.

It is to be emphasized that in short wave diathermy there should be no clothing between the electrode and the skin. A burn received from a treatment by short wave diathermy when the clothes have not been removed might readily provoke a medicolegal situation. After the treatment it is important to inspect the skin of the part treated.

The regulation of dosage with short wave diathermy is an even more empirical procedure than with conventional diathermy. The milliammeter is connected to the oscillatory circuit of the apparatus and serves chiefly as an indicator that electrical energy is passing. It will also indicate that in a certain position of the controls, when the patient's circuit is tuned to the oscillator circuit, there is a maximum flow of energy in the treatment field.

CONTRAINDICATIONS

It is important to keep the contraindications for diathermy in mind. The local application of high frequency currents is contraindicated in the case of certain acute inflammatory processes, such as acute nondraining cellulitis and acute infectious arthritis, or any condition in which there is a tendency to hemorrhage, such as a gastric ulcer; over areas in which the appreciation of heat has been impaired or lost, as in the case of certain peripheral nerve injuries; through the abdomen, pelvis or lower part of the back during pregnancy; during menstruation or thirty-six hours before or after menstruation, and over areas where a malignant growth is suspected.

INDICATIONS

Contusions.—The early application of cold by compresses or ice bag will reduce ecchymosis, swelling, pain, tenderness and limitation of motion. After the first twenty-four hours, infra-red radiation and medical diathermy may be applied to increase activity of the circulation.

Muscle Strains.—These are treated like contusions with regard to the application of cold and heat. For muscle strains, diathermy must be applied for only a short time and at a low intensity for the first treatment, as it may cause an increase in the swelling.

Myositis Ossificans.—With muscle injuries there is always the possibility of the development of myositis ossificans, which tends to progress unless the affected area is properly treated. The treatment consists primarily in rest and increase of local circulation by various means, especially diathermy.

Sprains and Dislocations.—There are various degrees of sprains, and treatment varies in direct proportion to the damage done to the soft tissues. Immediate walking may be advised in cases of slight sprain of the ankle, while rest in bed may be indicated in cases of severe sprain.

A mild sprain of the ankle can be satisfactorily treated by strapping to prevent lateral motion but not plantar and dorsal flexion. The efficacy of this method depends on the efficiency of the strapping. It is thought that plantar and dorsal flexion have a direct effect in promoting return of circulation and prevention of adhesions.

In the treatment of some sprains and dislocations, fixation by a removable plaster splint and the daily application of heat and massage may be preferred. In sprains or dislocations, ligaments are torn and muscles, blood vessels, nerves, tendons and the synovial membranes of the joint are injured; there are hemorrhage from the torn vessels, swelling and muscle spasm. Inflammatory action is noted with heightened local metabolism and elevation of temperature. For immediate treatment, therefore, local applications of cold with rest, proper compression, bandaging and elevation are indicated. After the first twenty-four to forty-eight hours, there are local edema and decreased local metabolism. Then the treatment should consist in removal of the splint and bandage followed by the application of external heat or diathermy, and this is usually succeeded by massage and exercise to produce a free flow of blood through the part. One must not forget, however, that other methods of applying external heat are available, such as those described in other chapters of the Handbook of Physical Therapy concerning heat. Among other important measures following the heating of these parts is the stimulation of circulation by massage and exercise.

Bursitis.—The first attack of bursitis can usually be relieved by physical therapy in about two weeks. The part should be placed at rest. For acute bursitis, infra-red radiation from a luminous source is given for thirty minutes at least twice daily and short wave diathermy is applied for twenty minutes once daily. As the pain diminishes, careful massage and relaxed motion should be employed; later, active exercise is started. Acute subacromial, radiohumeral, olecranon and prepatellar bursitis are treated in this manner. In a few cases, diathermy may aggravate the pain. In these cases it may be necessary to put the patient to bed and apply continuous moist heat.

For chronic subacromial bursitis, conservative measures, such as rest, infra-red irradiation, short wave diathermy, massage and exercise should be tried before operation is considered. In some cases of chronic involvement with severe pain the shoulder should be immobilized in an airplane splint. In this form of bursitis, calcified deposits may form without any apparent cause, are often fragmented and may disappear spontaneously. It is believed that diathermy may aid in the absorption of such deposits. When conservative measures fail, operative removal of the bursa and its calcified deposit is advised.

Tenosynovitis.—Traumatic tenosynovitis most commonly affects the tendons of the wrist, the achilles tendon and the long head of the biceps. The treatment is to immobilize the joints whose motion causes pain in the tendons. The splint is removed and short wave diathermy is applied for twenty minutes once daily, followed by radiant heat once or twice daily for twenty minute periods. It may be advisable to use motion in a whirlpool bath to prevent adhesions.

Rheumatic, gouty and gonorrheal tenosynovitis are treated in the same manner as the traumatic form. Pyogenic tenosynovitis is a surgical problem and diathermy is not used in its treatment.

Chronic Arthritis.—This is not a disease of certain joints but rather a systemic illness, in which there may be disturbances of the circulation, general metabolism, gastrointestinal tract and nervous system. The syndrome of chronic arthritis includes the nerve, muscle and joint diseases called neuritis, myositis, fascitis and arthritis, according to the part affected. Local and general applications of heat have perhaps their most extensive varied usage in the treatment of chronic arthritis. In chronic arthritis the circulation in the more narrow vessels, especially at the periphery, is usually diminished. The involved areas may be cold and clammy, but they may also present rubor, dolor and color. In any event, local heat may prove of great value, as may systemic applications, because of the

alteration and improvement in the circulation brought about. Great care should be exercised in the application of heat in cases of hypertrophic arthritis, since heat may constitute a form of trauma which aggravates the conditions already present. When indicated, however, local application of heat should be made from two to four times a day in the patient's room to produce an adequate increase in circulation, and, if medical diathermy is used, it may be supplemented with the former treatment. When medical diathermy is used for chronic arthritis it should be used for a short period with low intensity for the first few doses, because sometimes it causes an aggravation of the local symptoms. Clinical benefit, however, has been observed so often from diathermy that one should always give it a trial.

Myositis and Myofascitis.—These conditions are inflammations of the muscles characterized by pain on motion, spasm and tenderness on pressure. When the inflammation involves the lumbar muscles, it is known as lumbago; the intercostal spaces, pleurodynia, and the neck muscles, torticollis. In the local treatment of acute forms, rest and the application of heat are recommended. This heat may be applied by hot compresses, continuous moist heat, infra-red radiation from a luminous source or medical diathermy.

Fibrositis.—This has been defined as a swelling and proliferation of the white fibrous tissue anywhere in the body in response to injury or very toxic infection, with a secondary effect of pressure on arterioles and nerve filaments. Many American clinicians have been loath to recognize fibrositis because its morphologic lesions are ill defined and its symptoms subjective. Those who do recognize it by its nodules in the muscles classify most forms of muscular rheumatism as fibrositis and treat the condition with deep massage. Heat, massage and exercise are used as adjuncts in the treatment, and diathermy may be used as one of the methods of giving heat.

Fractures.—The principles of fracture treatment are restoration of anatomic form, maintenance of alinement and fixation of the fracture during the period of union, and maintenance and development of function. (For a more complete discussion, see "Physical Therapy in the Treatment of Fractures," by Dr. Frank D. Dickson, included in the Handbook of Physical Therapy.) Heat, massage and mobilization are important physical therapy measures, the object of which is to increase the activity of the circulation, to prevent adhesions in muscles and joints, to prevent muscular atrophy and later to increase muscle strength. The heat, of which one method of production is medical diathermy, is used mainly as an adjunct to massage and exercise.

Genito-Urinary Conditions.—Medical diathermy is used by a few clinicians as one of the methods of applying heat for the treatment of epididymitis and prostatitis.

Pelvic Infections.—Some gynecologists use medical diathermy as one of the methods of applying heat in cases of pelvic infection, although most gynecologists believe that a low degree of heat usually suffices.

Respiratory Diseases.—The chest compress is used by some clinicians to apply heat in the treatment of bronchitis. If the patient is in the hospital, it is believed that medical diathermy is more effective and easier to apply. With bronchitis, this method relieves the pain and soreness in the chest, reduces the viscosity of the secretions and thus makes expectoration easier; it also relieves the coughing.

It has been observed that, in the management of pneumonia, medical diathermy does seem to be of definite benefit in reducing the severity of thoracic pain. This symptomatic relief is important. The main factors concerned in the production of anoxemia are the passage of blood through the unaerated portion of the lung and shallow breathing. The shallow breathing may be due to pleuritic pain restricting the respiratory excursions. The relief of this pain by diathermy increases the respiratory excursions and this may be the explanation for the decrease in cyanosis that is usually noticed. There is no evidence that medical diathermy has a specific action on the pneumonic process.

Gastrointestinal Diseases.—For such conditions as acute enteritis, spastic colitis and simple catarrhal jaundice, abdominal warmth is suggested as an aid in treatment. An electric heating pad or a hot water bag kept on the abdomen for hours at a time is useful therapeutically. Infra-red irradiation is a convenient way of applying heat; diathermy, if mild and properly applied, is also of benefit.

Inflammation of the Peripheral Nerves.—With the various forms of neuritis, radiculitis and neuralgia, applications of heat may allay the inflammation and the pain. For deep penetration of heat into the tissues, medical diathermy may be used as a method of applying heat as an adjunct in general treatment. In the case of acute neuritis or acute radiculitis, it is believed that the first two treatments should be given at half the patient's tolerance for about ten minutes to see whether there is any aggravation of the symptoms.

Acute and Chronic Sinusitis.—Infra-red irradiation and medical diathermy are useful adjuncts to other treatment after adequate drainage has been established. Medical diathermy is of value as an aid in the relief of pain; the frontal and maxillary sinuses are the ones most suitable for treatment.

Eye Diseases.—The indications for medical diathermy are by no means well established. It is believed that this treatment may be used to relieve pain from chronic keratitis, neuralgia, herpes zoster and iritis.

Suppurative Processes.—Short wave diathermy has been advocated in the treatment of suppurative lesions with external drainage and doubtless will be of aid in this treatment. However, sufficient comparative study is not available to determine whether short wave diathermy is more effective than the simpler forms of heating.

SUMMARY AND CONCLUSIONS

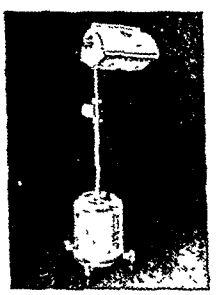
While there appears to be no great difference between the effects produced by conventional and short wave diathermy, short wave diathermy seems to produce deeper, more uniform heating and is more readily applied, although the control of dosage is more difficult than with conventional diathermy. Nevertheless, burns are less likely to be produced in short wave diathermy.

So far as competent investigators have been able to determine, there is no demonstrable selective thermal action in the living body. The Council has accepted certain short wave apparatus, which are listed in a booklet "Apparatus Accepted by the Council on Physical Therapy of the American Medical Association." Physicians are urged to read this booklet before purchasing an apparatus. The Council requires certain definite tests for deep heating before accepting an apparatus, and its survey of the machine gives the results of these tests as well as the efficiency and accepted technics for use of the machine.

Clinical observations, however, have not indicated that the penetration of heat induced by short wave diathermy presents advantages not obtained by con-

ventional diathermy. In the light of present observations, no specific physiologic effects other than those attributable to heating have been substantiated.

The consensus (particularly of those who have performed careful experiments) would seem to be that the effect of various wavelengths between 3 and 30 meters is approximately the same. There are apparently no specific bactericidal effects other than those attributable to heat, either in vitro or in vivo. There is no reason to believe that treatments of five minutes or less have any marked action other than a psychic one.



The chief advantages of short wave diathermy over conventional long wave diathermy are its ease of application and the lessened danger of burns.

LUXOR PROFESSIONAL MODEL ALPINE LAMP ACCEPTABLE

Manufacturer: Hanovia Chemical and Manufacturing Company, Chestnut Street and N. J. R. R. Avenue, Newark, N. J.

The Luxor Professional Model Alpine Lamp contains a high pressure, low voltage quartz mercury arc burner and is designed for therapeutic use in hospitals or offices. It is available for operation on alternating current (Model S) and direct current (Model E). The burner is placed inside a processed aluminum reflector so designed as to keep the hood temperature cool. Hinged doors on the hood intercept light and control, within limits, the size of the area irradiated. By rotating the hood, the angle of projection of light may be altered. A steel tape measure is attached to the side of the hood to measure distance from burner to patient.

The hood is mounted on a four-pod base resting on four rubber-tired ball-bearing casters and is adjustable within limits of 53 inches and 68 inches from the floor. When fully telescoped, the overall height of the lamp is 57 inches. The shipping weight of the entire unit is approximately 130 pounds. It is finished in ivory-colored enamel.

Luxor Professional Model Alpine Lamp.

Burners for both alternating and direct current are similar to an extent. Each comprises a transparent fused quartz tubular vessel provided with metal lead-ins for the electric current which are sealed vacuum tight directly to the quartz. The alternating current burner has solid, self-heating electrodes. The burner for the direct current has a mercury pool cathode and a solid incandescent anode. In both models the radiant energy is generated by means of an electric discharge through mercury vapor. The spectrum of radiant energy is that of mercury vapor and the spectral energy distribution of both lamps is that of the high pressure mercury arc in quartz. The load wattage for Model S (alternating current) is 450, for Model E (direct current) is 310. Electric current is supplied to the burner in Model S from a transformer through a reactor; in Model E through a rheostat.

The intensity of the ultraviolet radiant energy at 30 inches from the burner for wavelength 3,130 angstroms and shorter is 1,200 microwatts per square centimeter. This energy will produce a first degree erythema (mild reddening) on the average person after an exposure of one minute. The alternating and direct current lamps are equal in intensity and erythema production.

Reports from clinics indicate that intensities lower than those produced by this lamp are effective in the protection and cure of rickets and infantile tetany in children.

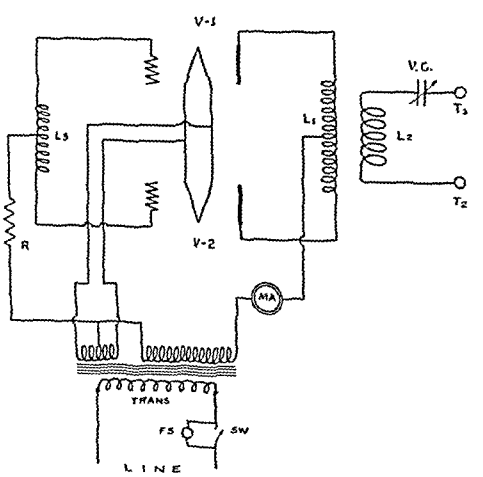
The unit was tried out in a clinic acceptable to the Council and reported to give satisfactory clinical service. The minimal erythema time at 30 inches was three quarters of a minute. The burner lighted instantaneously and the warm-up period was short as compared to older types of ultraviolet units.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Luxor Professional Model Alpine Lamp for inclusion in its list of accepted devices.

HIGH TENSION SHORT WAVE APPARATUS, MODEL RF-1, ACCEPTABLE

Manufacturer: High Tension Electric Corporation, 118 West Twenty-Second Street, New York.

The High Tension Model RF-1 Short Wave Apparatus is recommended for medical and surgical diathermy. It is a portable model, equipped with pad and cuff electrodes and electrosurgical accessories. The unit proper is 19 inches long by 12¼ inches high by 11½ inches deep. The total weight of the unit and subcabinet is 92½ pounds and the weight of the unit alone, without subcabinet, is 41½ pounds.



High Tension Short Wave Apparatus, Model RF-1.

Two self-rectifying tubes are utilized in a push-pull oscillator circuit of modified design. The wavelength is between 15 and 15.6 meters. The patient's circuit is inductively coupled to the oscillating circuit. Current to the patient is regulated through a tuning condenser.

The maximum power required to operate the RF-1 Model is approximately 750 watts. The output power is about 275 watts as determined by the lamp load method.

The final transformer temperature of the unit after operation at full load for two hours was 71 C. The final temperature at the top of the cabinet over the transformer was 57.5 C. The final temperature at the bottom of the cabinet was 49 C. These temperatures are within the limits of safety.

Evidence was submitted by the firm to substantiate tissue heating claims made for the Model RF-1 Short Wave Diathermy Apparatus as applied to the living human thigh. Three male subjects were used in these tests. Temperatures before and after the twenty minute applications were taken by means of a hypodermic thermocouple calibrated against a thermometer standardized by the National Bureau of Standards. The skin surface temperatures and the muscle temperatures were observed. The electrodes were 21½ inches long and 2¼ inches wide. The average distance from center to center of the cuffs was 8.6 inches.

Schematic diagram.

The cuffs were operated from the skin by means of felt pads and towels to 1 1/10 inches. The average thigh circumference was 18.7 inches. The average room temperature was 70 F. and the humidity was 51 per cent.

Averages of Six Observations, Cuff Technic

Deep Muscle		Rectal	
Initial	Final	Initial	Final
97.8	106.1	99.1	99.3

Using the cuff technic only, the Council on Physical Therapy voted to include the High Tension Short Wave Apparatus, Model RF-1, in its list of accepted devices.

THE CASE OF BRINKLEY VS. FISHBEIN

PROCEEDINGS OF A LIBEL SUIT BASED ON AN ARTICLE PUBLISHED IN *HYGEIA*

(Continued from page 1968)

TESTIMONY OF DR. MORRIS FISHBEIN

Dr. Morris Fishbein stated his qualifications as a physician and as a writer. He then described the work of the American Medical Association, including the work of the various councils, bureaus and departments. He then described fully THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and its distribution; next, how a physician becomes a member of the American Medical Association, and the nature of membership; then the foundation of *Hygeia*, its purposes, circulation, income and loss.

The evidence then proceeded:

Q.—Doctor, referring to the article upon which this suit is based, you were the author of that article, weren't you? *A.*—Yes, sir.

Q.—Will you tell us from what source or sources you procured the information and material for that information? *A.*—Most of the material was secured from the files of the American Medical Association, which are maintained constantly, which I have described, by the Bureau of Investigation; the Bureau of Investigation, which was established in 1905, maintains permanent files containing the records of all persons, devices, drugs and similar promotions which come under its attention. Most of the material regarding the plaintiff was on file in the records of the Bureau of Investigation; there were also on file in that record the complete reports having to do with the work of the plaintiff issued by him from time to time at his various addresses; there were also on file the records of various hearings that had been held in various states relative to revocation of license.

Mr. Morriss Jr.:—We object to the witness's statement of these various matters as his conclusion and opinion of what they might be.

THE COURT:—Isn't it the rule of evidence that if the party writing the article honestly believes it to be so, why, it may be tendered to mitigate damages?

Mr. Morriss Jr.:—But he can't tell what is in some instrument or letter that he doesn't produce.

THE COURT:—I shouldn't think so, not as proof of the truth of those facts, but he can testify as to the sources from which he got the information he put in the article.

Mr. Morriss Jr.:—He can't tell what he got, and he has now been stating that, and we move to exclude it. We agree with the Court that he is entitled to state where he got it from, but not the contents of the written matter.

THE COURT:—I didn't understand that he had stated the contents; he said he got it from certain records of hearings where the matter was regarding the revocation of license.

Mr. Morriss Jr.:—That is stating the import of the information.

THE COURT:—I think this is quibbling; the plaintiff was interrogated in regard to that. I will overrule the objection.

Mr. Morriss Jr.:—Note our exception. It calls for a conclusion and opinion of the witness.

A.—I had also available letters sent to headquarters office by persons relative to the plaintiff; I had also records of conversations and reports with persons relative to the plaintiff.

Q.—Now, Doctor, it is alleged in the complaint that this article was printed in the *Hygeia* of February 1938, and was that an original article for the February number of *Hygeia*? *A.*—The article appeared in two parts, the first part in January and the second part in February.

Q.—Now, we notice that the article in the January issue is headed, as counsel has shown, "Modern Medical Charlatans"; is the article declared upon and which is published in *Hygeia* for the following month, February 1938, a continuation of that series of articles on that subject? *A.*—It is.

Q.—Doctor, do you know John R. Brinkley in person? *A.*—No, sir.

Q.—Have you ever met Dr. John R. Brinkley before this trial? *A.*—No, sir.

Q.—Of course, you had never had any dealings with him? *A.*—No, sir.

Q.—What was your feeling toward John R. Brinkley before writing the article? *A.*—It is a part of my duty as editor of THE JOURNAL and of *Hygeia* that—

Mr. Morriss Sr.:—Just a moment, may it please the Court, that is argumentative.

THE COURT:—It is not responsive to the question.

Mr. Morriss Sr.:—Yes, but it is an attempted argument.

THE COURT:—Well, I sustain it. You will have to start over and answer the question. He asked you what was your feeling toward him. You are entitled to explain that, if you want to.

A.—My feelings would be, from a scientific point of view, quite negative; in other words, for a period of approximately about twenty-five years, week after week, month after month, we have published articles describing various patent medicines, nostrums, charlatans and promotions in the field of health, and in the course of that work there came to our attention the performances of the plaintiff, and in accordance with the usual carrying out of the work it becomes necessary then to discuss the performances of the plaintiff along with others in the same field.

Q.—Well, did you have any personal animosity toward Dr. Brinkley? *A.*—No, sir.

Q.—Well, now, Doctor, there has been something said during this trial about eclectic physicians and what is an eclectic physician? *A.*—There have been from time to time in the practice of medicine various fields of medical practice devoted to special—

Mr. Morriss Sr.:—There may be some limitation, but the answer as it starts out is not responsive, it is just a continuation of the answer.

THE COURT:—Everybody can't speak in absolute terms of definition, and if he wants to tell us in his own way what eclectic is, he can do it.

A.—I might point out there was one school of eclectic physicians that existed 1,500 years ago, and that school of eclectics is, obviously, obsolete; more recently a school of eclectic was established about the time of the Revolutionary War of the United States, and it reached its height about 1850, and from that time on eclectic medicine began to decline, representing eventually a certain group of doctors that believed primarily in plant remedies and believing that for each disease there was a plant remedy; certain schools remain that teach that belief.

Q.—And one of those schools was the Kansas City Eclectic Medical College, is that right? *A.*—Yes, sir.

. . . . . .

Q.—In this article there is some mention made by you of the plaintiff's activities in performing operations by the transplantation or implantation of goat glands in a human being, and from what sources did you obtain that information? *A.*—Most of the information from the pamphlets issued by the plaintiff himself, some of the information through personal visits to the state of Kansas and occasional conversations with persons who had been directly familiar with such transplants.

Q.—Now, there is also some mention made in the article of the plaintiff conducting the so-called medical question books, and from what source or sources did you receive that information? *A.*—I heard the plaintiff repeatedly as he made his radio broadcasts, and I had also opportunity to see transcripts of his broadcasts, and I was familiar also with the record of the appearances before the Federal Radio Commission.

Q.—That was in connection with the revoking of the plaintiff's radio broadcasting license? *A.*—That was in connection with the Federal Radio Commission's decision not to renew the license.

Q.—Now, there is a statement in the article declared upon in regard to the plaintiff's license to practice medicine in Kansas being revoked. *A.*—Yes, sir.

Q.—From what source did you receive that information? *A.*—The records of the Bureau of Investigation contain a complete statement relative to the revocation of the license in Kansas; I obtained information also regarding that from Dr. C. C. Nesselrode, who investigated the work of the plaintiff at first hand and also from Dr. J. F. Hassig, who is a member of the Kansas Board.

Q.—Who is Dr. Nesselrode? *A.*—Dr. Nesselrode is a physician in Kansas City, Kansas, who has himself for the Kansas Board witnessed an operation by the plaintiff in Milford, Kansas.

Mr. Morriss Sr.:—That is obviously the merest, rankest hearsay, and we move to exclude the statement.

THE COURT:—It may be that you know something more about it than I do, but it is my understanding that in these kind of cases the law is that a party accused of libel is entitled to state the sources where he got the information and what it was. I don't admit the statements of third persons for the purpose of proving the statements, but I admit it for showing that he received it from third persons, and if he wants to testify that he believed them and acted on them, I think it is proper evidence.

Mr. Morriss Sr.:—He testified he received it from Dr. so and so, who witnessed—

THE COURT:—It may be that he ought to say that Dr. Nesselrode told him.

Mr. Morriss Sr.:—Then, we have no objection to that.

A.—I will revise the statement that I received the statement from Dr. Nesselrode, who said he had witnessed the operation.

Q.—You believed that statement, did you, Doctor? *A.*—Yes, sir.

Q.—Now, I notice that in the article there is the statement in regard to the compound prostate operation of the plaintiff, and I will ask you from what source or sources you received that information? *A.*—I have read the records in which the Kansas State Board of Medical Registration received the report from Dr. Nesselrode on which basis that Kansas State Medical Board revoked the license, and the report of Dr. Nesselrode describing the four phase compound operation as given to Dr. Nesselrode, according to his statement, at the time when he watched the plaintiff perform the procedure on two patients.

Q.—Now, it is said here, as part of the article that I am referring to, that Dr. Brinkley has a high pressure man in his front office to make sure that those who come to the hospital will have the money to pay in advance for the work, and from what source or sources did you receive that information? *A.*—In the first place from a patient who, having submitted himself to a procedure by the plaintiff, later visited the Mayo Clinic in Rochester, Minnesota, and made a direct statement of his financial relationship at the time when he visited the plaintiff; second, from the repeated statements of the plaintiff in broadcasts as to the financial ability of those requested to come to his hospital.

Q.—Now, it says here, Doctor, "they are able to develop mortgages, loans, and conversion of securities in order to permit the patient to pay on the nail for what he is going to get," and from what source or sources did you obtain that? *A.*—From the statements of the patient already mentioned, and also from the statement of the business manager, I believe, who was here yesterday, for the present time; prior to that time from the statement made by this patient and the statements made on the radio as to the financial ability of those coming to the hospital.

Q.—And you believed those statements, did you, Doctor? *A.*—I believed that the plaintiff meant what he said when he said that he wanted them to be financially able.

Q.—Now, it says "most of the business, however, seems to come by way of the mail, and it is time for the Post Office Department to do something in regard to the use of the United States mails by John R. Brinkley in his defrauding of the public," and from what source or sources did you receive that information? *A.*—From listening to the broadcasts of the plaintiff on many occasions, and on one occasion in which the plaintiff said in my own hearing to the people to send him merely a bill with their name on a sheet of paper mentioning the broadcast, but not to describe the symptoms, merely send the name on a piece of paper with a bill; in fact, if I can remember the exact words, he didn't have time to go into the symptoms and that he would send a bottle of medicine that would be of help to them.

Q.—Now, it says here, Doctor, in your article "another of the Brinkley schemes is to sell to the patient who comes to his lair five ampules of his remedy for postoperative treatment at a cost of $100. These the patient is supposed to take home in order that the contents may be injected into him by his selected doctor. When an analysis of the selected ampules was made, it revealed that they contained a solution of approximately 1 drop of indigo to 100,000 parts of water—about what you would get by throwing a bottle of bluing into Lake Michigan." from what source or sources did you receive that information? *A.*—Letters, as

I have said, come in many thousands to the headquarters of the Association from physicians and from the public inquiring about all medical matters in the public eye, and in the course of our work there came letters from several physicians indicating patients had returned to their home town bringing along—

Mr. Morriss Jr.:—We object to the statement of the letters as not being the best evidence.

THE COURT:—Overruled.

Mr. Morriss Jr.:—Note our exception. It is hearsay.

A.—Letters had come from physicians indicating their patients had returned home bringing along certain ampules, these patients requesting the doctor to inject the material into the patient as a part of the post-operative treatment; one physician stated definitely that his patient had said to him that he had paid $100 for this material. These letters were sent to the Division of Drugs, Foods and Physical Therapy where Dr. Leech, as a previous witness has described, is director, and Dr. Leech requested the physicians to send the ampules, which have been produced in court, and these ampules were turned over by Dr. Leech to Dr. Schoeffel, who then made, as he has described, a series of tests to determine the content of the ampules; then, to describe the matter in such form that any one might understand the relative value of the contents of this ampule the description was made as reported in the statement.

Q.—Doctor, how did you conclude that this solution, which has been analyzed in the Chemical Laboratory and known as 1020, is about what you would get by throwing a bottle of bluing into Lake Michigan, as you stated in this statement? *A.*—The report was made by Dr. Schoeffel to Dr. Leech, who is the director of the laboratory and also a chemist, and Dr. Leech conferred with the director of the Bureau of Investigation, and the article published, as a majority of contributions are, many of our articles are, several of the authorities in the headquarters office contributing; and Dr. Schoeffel has shown that the amount of material in the ampule of a solid character was so infinitesimal as hardly to have any appreciable effect. Now, I didn't personally throw a bottle of indigo into Lake Michigan, but the analogy, I believe, is clear.

Q.—Now, Doctor, what is meant by the medical term "isotonic?" *A.*—An isotonic solution is a solution of essentially the same concentration in solid terms as the human blood, and hypertonic is one of greater concentration of solid materials than is the human blood, and hypotonic is one of lesser. If there is any further question, it is customary to inject isotonic solutions into the blood in order to avoid serious reactions. Hypertonics will produce a reaction in the blood, as will also hypotonics.

Q.—What result will hypotonic produce as compared with hypertonic? *A.*—It is associated with an inflammatory reaction of the blood vessel wall.

Q.—Do I understand you to mean that a solution that is injected intravenously should be isotonic? *A.*—Unless for some specific purpose the physician wishes to produce an inflammatory reaction, as he might, for example, in obliterating a blood vessel.

Q.—Now, it is said here in this article, Doctor, "the evidence assembled indicates that at various times Brinkley has made as much as $55,000 a week from his various quackeries. He has been the possessor of three fine yachts," from what source or sources did you obtain that information, Doctor? *A.*—It evidently was brought out in the hearing before the Federal Radio Commission, and at that time there was a failure to renew the license, and there was something with reference to the annual income of the plaintiff; the question of yachts, and so forth, that is a matter of general knowledge, and it has been reported from time to time by various reporters and written up and described by them.

Q.—It says in this article, "he travels abroad and returns to this country in the finest suites on the finest boats, accompanied by his family and the little boy's tutor. On the vessel going and coming neither he nor Mrs. Brinkley engage in conversation with the passengers," and from what source or sources did you obtain that information? *A.*—From two sources: in the biography the statement is made definitely that in a previous visit abroad the plaintiff was shunned.

Q.—Is that the trip to China that was referred to here this morning? *A.*—That was here this morning, and the second source was the personal observation when I returned myself from abroad in August 1937.

Q.—You were on the same boat as Dr. Brinkley? *A.*—I was.

Q.—And that was on the *Normandie* was it? *A.*—Yes, sir, it was.

Q.—And that was about along in August 1937? *A.*—Yes, sir, it was.

Q.—Now, Doctor, in preparing this article for publication in the magazine *Hygeia*, did any one assist you? *A.*—The material was supplied to me by the Bureau of Investigation, by the Division of Drugs, Foods and Physical Therapy, by various divisions of our library department, where material is accumulated, the records having to do with medical licensure and the Council on Medical Education and Hospitals; the article once written, as all articles are, was then sent to an assistant editor or manuscript editor who reread and in spots re-edited the article; then the article went to the proof room where it was read in proof and returned, then, the article went to three associate editors, each of whom also read the article and made various suggestions, and the final article represents, therefore, an item written on my own responsibility, but, to that extent, with the assistance of others in the office.

Q.—And by article, you mean, Doctor, this entire series of articles in both the January and the February 1938 issues of *Hygeia*, do you? *A.*—Yes, sir.

Q.—And, of course, that series of articles, Doctor, refers to various people other than Dr. Brinkley, isn't that right? *A.*—Yes, sir.

Q.—What I mean by that, Dr. Brinkley is just one subject of a series of articles on a series of subjects; that is, he is one person? *A.*—Yes, sir.

Q.—Now, Doctor, it said in the article here at the beginning, "Without anything resembling a real medical education, with licenses purchased and secured through extraordinary manipulations of political appointees, and with consummate gall beyond anything ever revealed by any other charlatan, Brinkley has achieved an enormous success financially," and from what source or sources did you obtain that information for the article? *A.*—The sentence in question refers to several points. First, the point "without anything resembling a real medical education," an accomplished medical education as of the period 1910 or 1911 or 1912 included a year or two of college education, four years of medical education in a recognized medical school, what Mr. Petermeyer described, I believe, as a class A school. Next, the internship in a hospital recognized as suitable for giving an intern a reasonable amount of education and experience; the plaintiff had no such medical education, according to any records that are anywhere available. As to the enormous financial success, the records of the hearing before the Federal Radio Commission indicated the income of the plaintiff at that time, and he, himself, has testified as to his income during 1937—

Mr. Morriss Sr.:—Evidently that, now, must be an argument, because he didn't have that testimony before him when he wrote the article.

THE COURT:—Yes, sir.

A.—According to the admitted ownership of three yachts and a hospital and the living habits of the plaintiff, it was apparent that his financial competence was considerable, at least as compared with that of the average physician, so that he might be said in comparison with the average physician to have made an enormous financial success.

Q.—What do you consider the average amount earned by a physician, as you have stated here?

Mr. Morriss Jr.:—That would be incompetent and a conclusion and an opinion.

THE COURT:—Overruled

Mr. Morriss Jr.:—Note our exception.

A.—There have been reports as to the average income of a physician in the United States, at least three such reports, one made by the United States Government, one made by a committee on the costs of medical care and one made by the Bureau of Medical Economics by the American Medical Association, and all three reports agree that the approximate average income of a specialist in the United States is between $6,500 and $7,000 per year, and the average income of a general practitioner between $3,000 and $3,500 per year.

Q.—Now, while we are on the subject of specialists, what is a specialist in medicine? *A.*—A specialist in medicine is a physician who limits his practice exclusively to a single system of the body or to a single form of medical procedure.

Q.—What qualifications does a specialist ordinarily have? *A.*—A specialist usually has taken special studies in recognized clinics or institutions having to do with the special branch of medicine which he pursues; he is usually a member of recognized scientific societies which are voluntary organizations of the men devoting their attention to such work; he may be the possessor of the certificate of an examining board in the specialty, because there are examining boards which examine men who claim special competency, and they certify to the fact that these men are qualified as specialists.

Q.—How would I determine whether or not a doctor is a specialist? *A.*—If you were to consult the directory of the American Medical Association you would find the schools of graduation, the membership in various special medical societies and also a statement as to whether or not he possessed the certificate of the examining board in his specialty.

Q.—What are some of these specialists' societies that you have referred to, name them, please. *A.*—There are approximately 200 such specialist societies. Concerning the specialties which the plaintiff states to be his specialty, there are the American Urological Association and the American Association of Genito-Urinary Surgeons.

Q.—What is the American Urological Association? *A.*—The American Urological Association is a voluntary organization of some hundreds of specialists who specialize in diseases of the kidneys, bladder, prostate and in various genital urinary diseases.

Q.—And what is the other society that you named, the American Association of Genito-Urinary Surgeons? *A.*—That is an organization consisting of men who specialize in surgical operations on the genital urinary tract.

Q.—Now, Doctor, will you tell us, if you know, whether or not men, that is physicians who specialize in these particular branches of medicine, are ordinarily members of such societies?

Mr. Morriss Jr.:—That is incompetent, irrelevant and immaterial to establish any issue in the case, and we object to it for those reasons, and it would be hearsay, and as to this plaintiff there is not the proper criterion.

THE COURT:—Overruled.

Mr. Morriss Jr.:—Note our exception.

A.—I would say that men recognized in the United States by their colleagues as competent in the field of urology and in the field of genital urinary surgery are usually members of these organizations.

Q.—Well, assume, Doctor, that the medical man holds himself out as being a specialist or a great urologist, would he ordinarily be a member of one or more of these societies that you mentioned?

Mr. Morriss Jr.:—We object to that as going over into a field of speculation, and for all of the other reasons.

THE COURT:—Overruled.

Mr. Morriss Jr.:—Note our exception.

A.—I would say that a man who has achieved prominence in the field of urology and in the field of genital urinary surgery is, in practically every instance, a member of one or the other, or both of these organizations.

Q.—All right, Doctor, now, this medical directory that you have mentioned as being printed and published by the American Medical Association, does that directory show by sign or symbol or in some manner the societies to which the medical men listed ordinarily belong? *A.*—It does.

Q.—So that a specialist or a man who holds himself out as a great urologist or a specialist, whose name is listed in that directory, if he belonged to either one of these societies it would be shown in that directory, wouldn't it? *A.*—It would.

Q.—So, in that manner you could obtain information as to any physician or surgeon as to the societies he belongs to? *A.*—I could.

Q.—By referring to the medical directory? *A.*—I could.

Q.—Now, Doctor, what proportion of the material used in compiling this article was received by you from the Bureau of Investigation, approximately what portion? *A.*—I would say approximately 70 to 75 per cent, three fourths of it.

Q.—Now, that bureau or department deals directly, doesn't it, with inquiries from people that write in regarding physicians? *A.*—Yes, sir.

Q.—That is, among other things, physicians? *A.*—Yes, sir.

Q.—And does the bureau keep a separate file for each of these physicians from whom—that is, of whom they have received inquiries? *A.*—It does.

Q.—Have you had a file on John R. Brinkley in that department for some time? *A.*—We have.

Q.—And is that department or bureau under your jurisdiction as editor of THE JOURNAL and as editor of *Hygeia*? *A.*—Not directly.

Q.—Well, is it connected in any way with the editorial department of these two magazines? *A.*—Yes, sir.

Q.—And in what way is it connected?

The witness then described the work of the Bureau of Investigation. The evidence proceeded:

Q.—Well, Doctor, before compiling this article, you didn't go out and investigate—

Mr. Morriss Sr.:—Don't lead the witness.

Q.—I will ask you did you go out and investigate John R. Brinkley to obtain this material for this article? *A.*—I had at various times been in the state of Kansas, I had at various times been in contact with investigations of the plaintiff in Kansas, and to that extent my knowledge was personal.

Q.—But what I mean is, most of this information came to the Bureau voluntarily? *A.*—By far most of this material came to the Bureau voluntarily from people who were inquiring and who sent along the material on which they based their inquiry.

Q.—Now, before compiling the—that is, when assembling that information and before compiling this statement did you or did you not believe the facts that you incorporated in this statement to be true? *A.*—I believed them to be true and I do believe them to be true.

Q.—Did you or did you not believe at that time the facts that are incorporated in this statement, believe it was a fair and impartial report of the information you had available at that time? *A.*—I do.

Q.—And by that you mean in your official capacity as editor of the *Hygeia* magazine? *A.*—I write always in my official capacity.

Q.—Doctor, we have offered and there has been received in evidence various and sundry exhibits, and I believe you looked at them at the table and are familiar with them? *A.*—Yes, sir.

Q.—Are those exhibits, that is, those pamphlets introduced in evidence here today, exhibits 9 to 38, do they contain the information or some of the information that you incorporated in this alleged libelous statement? *A.*—Yes, sir.

Q.—And did you base the statements that you made, either in whole or in part, upon the information that is contained in those pamphlets and other documents introduced in evidence here today? *A.*—Yes, all information which is contained in the article which I didn't personally see or take part in is based on documents which were available at the time the article was written.

Q.—Now, tell us what is meant by the word "quack"? *A.*—A quack is a person who makes extravagant and blatant claims.

Mr. Morriss Jr.:—That is what he means by it, but that is a matter for the Court to charge the jury as to what is meant by a quack, and it is a question of law.

THE COURT:—There are a great many definitions of "quack," and inasmuch as this man's motive is under question here, he is being sued for an amount for malicious libel, I think he is entitled to say what he meant by saying that.

Mr. Morriss Jr.:—The test is not what he meant.

THE COURT:—No, sir, but the test is what the average person in reading the article thinks; and I will so instruct the jury.

Mr. Morriss Jr.:—Note our exception.

A.—It is my own conception of a quack that a quack is a person who makes extravagant or blatant claims as to his ability in the field of medical science and in taking care of the sick.

Q.—Is that all? *A.*—That is the common, accepted definition, according to my knowledge of a quack.

Q.—Now, tell us what your definition of a "charlatan" is. *A.*—My knowledge of the word "charlatan" would take it to be in the vast majority of instances synonymous with the word "quack," and it means exactly the same thing.

Mr. Morriss Jr.:—The same objection.

THE COURT:—Yes, sir.

The witness described his interpretation of the term "recognized medical school" and the manner in which the American Medical Association investigates and lists hospitals.

The evidence proceeded:

Q.—How many lists of hospitals are published? *A.*—Three in the United States; one by the American Hospital Association, one by the American College of Surgeons and one by the American Medical Association.

Q.—By "lists of hospitals" what do you mean—describe it? *A.*—Hospital lists include what the American College of Surgeons calls acceptable hospitals; and the American Medical Association lists include registered hospitals and hospitals suitable for the training of an intern, and the American Hospital Association hospital list includes those holding membership in the American Hospital Association.

Q.—Do you know if the Brinkley hospitals are on the hospital lists that you refer to? *A.*—The Brinkley hospitals aren't on any of the lists.

Q.—Do you know if they have ever been on that list? *A.*—To my knowledge they have never been on any of the lists.

The jury was then excused from the court room, and the Court discussed with the attorneys the question of the admissibility of evidence as to the Brinkley marriage and divorce.

March 24, 1939

Dr. Fishbein resumed the stand, and there was offered in evidence a deposition by Dr. Nesselrode, having to do with his witnessing an operation performed by Brinkley in Kansas. Dr. Fishbein stated the extent to which he remembered the statements made by Dr. Nesselrode and also the deposition.

The evidence then proceeded:

Q.—Now, Doctor, you heard the testimony yesterday of the chemist here in regard to his analysis of form 1020? *A.*—I did, yes, sir.

Q.—And were you previously familiar with that analysis, doctor? *A.*—I was.

Q.—And for how long a time have you been familiar with that? With that analysis made by this chemist? *A.*—Since the time when it was completed.

Q.—Well, did you read his analysis or consider it? *A.*—I did.

Mr. Morriss Jr.:—We object to that, and we ask that all of the testimony be stricken because it appears from something in writing, and we object to it as not being the best evidence.

THE COURT:—He simply asked him if he read it. The chemist testified yesterday to his analysis and the fact that it was given to Dr. Fishbein.

Mr. Morriss Jr.:—But we are now getting at it, sir, and the doctor is attempting to testify what information he had before him and that was by a report in writing.

THE COURT:—I will overrule that portion of it. I think it is too technical.

Mr. Morriss Jr.:—Note our exception.

Q.—Now, Doctor, will you tell us in plain words so that we can all understand it what ingredients of one of these ampules or the ampules, the contents of which were analyzed by the chemist, just tell us in plain words what they were.

Mr. Morriss Jr.:—He couldn't do that. At most he can say what the other man told him and inasmuch as the report is in writing, and it is the best evidence—

THE COURT:—The chemist sat up here and told us what he found in the ampule and the doctor heard him do it, and any doctor could be asked to state in plain words what it was, if he knew.

Mr. Morriss Sr.:—If he was asked if he knew.

THE COURT:—You heard the chemist say what was in it and Dr. Fishbein heard him say it, and he could ask him that way, assuming that the ampule had in it what Dr. Schoeffel said in plain words, what it is. The testimony of Dr. Schoeffel was so highly technical it was difficult for the Court or the jury to get it.

Mr. Morriss Sr.:—But the witness's testimony must stand for itself and it must not be explained by anybody else, that is the usual rule.

THE COURT:—Whenever a witness gives evidence of a highly technical nature other witnesses can tell what it is in plain words so the jury can understand it. I will overrule the objection.

Mr. Morriss Sr.:—Note our exception.

A.—The analysis indicated that the contents of the ampule, which was the little glass bottle, was essentially 20 cc. of fluid, and 1,000 cc. makes a liter, and a liter is about a quart, and it contained approximately 20 cc., which is, as you can see, one fiftieth, or less, of a quart. This was essentially of the character of distilled water, except for an infinitesimal, a very tiny amount of coloring matter, very small indeed, in fact, so small it was necessary to have the services of a microchemist, which is a chemist that deals in very small materials, of which Dr. Schoeffel is one of ten, to make an analysis of small materials that were said to be in the solution, and he also found traces, as shown by the use of spectroscopic technic which is a technic in which one burns a certain amount of solid matter and causes the light to pass through a prism and then it distributes a colored scale on a chart, and on that technic he discovered a very small amount of halogen, and this was chlorine, about the same as common table salt, which is a contamination of the dye substances in the indigo field; and inasmuch as it was indicated that the ampule was said to contain a very minute amount of hydrochloric acid a search was made for that substance, but the indication of the presence of that substance was so minute that the explanation was offered that the walls of the glass had absorbed, perhaps, most of that substance, so that what the patient got exactly was a solution of the distilled water with an infinitesimal amount of dye substance and halogen or chlorine substance. Is that clear?

Q.—Yes, sir. Doctor, there have been many questions asked here the information to cover which has been taken from a book entitled "The Life of a Man," and I think it is by Clement Wood; in other words, a biography of John R. Brinkley, and I will ask you if before preparing this article you read the book "The Life of a Man"? *A.*—I read a copy of the book which was sent to me inscribed by the author as a presentation.

Q.—Now, Doctor, will you tell us what the common custom and practice among physicians in the United States is with regard to advertising, and I will say advertising in the field of medicine? *A.*—It is the common custom of physicians in the United States not to advertise their qualifications, their services or the price of those services in any way to the public.

Q.—And why is that, Doctor.

Mr. Morriss Jr.:—That would be a conclusion, if the Court please, on the part of the witness.

THE COURT:—He can state his opinion.

Mr. Morriss Jr.:—We think it is an improper conclusion and an opinion, and we object to it as such.

Mr. Harrell:—I submit, your honor, the witness has already testified and qualified as an author on medicine.

THE COURT:—I will overrule the objection.

A.—The common custom among physicians almost since time immemorial is to abstain from advertising, as described in the innumerable books, as well as in my own opinion, for the protection of the people, since it should be apparent at once that the physician who advertises and states in his advertising exceptional qualifications which he may or may not possess, and since there is no regulation of advertising of this character, the step would be to bring to the physician's consideration numbers of people who would come, not because of merit of his work, but primarily because they believed his own statement as to his special qualifications or to the fees which he charged and said to be more or less, for example, than the fees of other physicians, or as to the results he had secured, which, of course, the public would have no way of knowing had actually been secured or hadn't been secured, and, then, the custom established by use of practice among physicians is that the relationship of the doctor to the patient is such that the doctor must not vaunt his special qualifications, the fees he charges, the nature of his services, in any way to the public.

Q.—Doctor, what is the custom and practice among the physicians and in the medical fraternity in the United States with reference to new discoveries of medical science or new discoveries in surgery and surgical technic in the performing of operations?

Mr. Morriss Jr.:—We object to that as immaterial and irrelevant to any issue in this case.

THE COURT:—Overruled.

Mr. Morriss Jr.:—Note our exception.

A.—It is a precedent among physicians which has existed since time immemorial, that inasmuch as the public health is of the greatest importance for the advancement of the people and the nation, a doctor shall give freely of his new discoveries or of his operations or of his knowledge to all of the medical profession the moment such discoveries are established in order that as many people as possible may be benefited by the discovery, and with the definite understanding that the doctor shall not personally derive a profit from his discoveries or from his inventions; thus physicians publish descriptions of new drugs, new operations and new discoveries in the field of medicine as soon as they are established in order that other physicians may know of these methods and be able to duplicate them for the benefit of the sick.

Q.—Doctor, can you tell us if Dr. Brinkley has ever revealed or has published for the benefit of the medical profession his surgical technic of this new operation he refers to, or has it been submitted to the profession for criticism? *A.*—As far as I know it has never been published in any medical periodical, nor has it been generally submitted to the criticism of the medical profession.

Q —Doctor, would you tell us, if you know, how many states of the union recognize graduates in medicine from eclectic colleges? A —At the last report, which was officially published, the particular college in Kansas City, the Eclectic—the College of Eclectic Medicine and Osteopathy, wasn't to my knowledge recognized by forty seven of the forty eight states in the union; in other words, there was only one state which recognized that diploma

Q —What state was that? A —The state of Arkansas

The cross examination follows

CROSS EXAMINATION

By Mr. Morriss Sr

Q —But, of course, that didn't mean that if they were licensed to practice they couldn't practice in those states, notwithstanding that they had taken that course of study among others? A —It meant they couldn't practice in any state of original jurisdiction over the first examination, in some instances

Q —I didn't ask you that, and will you please make it a practice instead of going into the long answers just answer my questions yes or no, as far as possible A —Yes sir

Q —I say that didn't mean if they had a license be it that they had made a study of that as well as other systems, they couldn't practice anywhere and the fact that they got a license or diploma from the Eclectic College didn't bar them from practice otherwise? A —It would bar them from practice in some states

Q —Regardless of whether they qualified otherwise? A —It would bar them

Q —Notwithstanding the fact they passed the other qualifications for getting a license, the mere fact they got a diploma in the Eclectic College would bar them, is that your testimony? A —The question is not clear

Q —Supposing they studied other systems and qualified themselves and could take the examinations and pass the tests, the mere fact that they had gone to the Eclectic School at one time would bar them, is that your idea? A —A license requires—

Q —Answer the question yes or no A —It can't be answered that way

Q —The mere fact that they had once studied at this eclectic school, would that bar them? Answer that yes or no A —It might bar them

Q —Would it bar them? A —It would bar them in many states

Q —Necessarily, the mere fact they had studied that system? A —Not the system, the school

Q —Suppose that some doctor had studied at various schools and the various systems approved in those states—

THE COURT —Counsel, in order to bring this matter before us, why suppose all of those things if there is no evidence to support it? Dr Brinkley's testimony is that he studied for three years at a school in Chicago and then he quit for several years, and then went back and took a year's course in the Eclectic School Is it the claim that he went anywhere else?

Mr Morriss Sr —Yes, sir

THE COURT —He never said so in the evidence

Mr Morriss Sr —It could be shown that he studied elsewhere

THE COURT —Why suppose the things if there is no evidence to suppose it?

Mr Morriss Sr —I am getting the viewpoint of the witness, is all

THE COURT —I know, but it would take too wide a range and I want to confine it to the evidence

Mr Morriss Sr —I am not going to take a wide range

Q —Would the mere fact that some doctor had studied at other schools and could pass any examination, would the fact, in the interest of science, that he had gone down and taken a course there, would that bar him in other states? A —It would bar him in some states

Q —That is your idea? A —That is the truth

Q —Have you ever practiced medicine? A —Yes, sir

Q —When? A —I have practiced medicine for the period from the time of my licensure—

Q —When was that? A —In late June 1912, until the time when I became assistant to the editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Q —When was that? A —Which was in late August 1913

Q —You mean you practiced medicine, then, how long? A —Slightly over one year

Q —You practiced medicine slightly over a year where? A —In the city of Chicago

Q —Whom did you office with? A —I was at that time—do you want my program day by day?

Q —No sir, just whom you were officing with? A —Dr Hektoen, and I was also associated with Dr George H Weaver and Dr George F Dick

Q —Now then, as a beginner you practiced about a year? A —That is about all

Q —And that is all the medical practice you have ever had? A —No, sir

Q —You have never been an active practitioner from that time on? A —You mean offering my services for pay?

Q —Yes sir A —No, sir

Q —You have never done that since then? A —No, sir

Q —That was from 1912 until some time in 1913? A —Exactly

Q —That you were offering to practice medicine? A —Yes, sir

Q —And, then, you became an employee with the Medical Association? A —I became assistant to the editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Q —That was employment, wasn't it? A —Yes, sir

Q —And, then, you have been with the Medical Association ever since then, is that right? A —Yes, sir

Q —And you have been editing this *Hygeia* how long? A —Approximately fifteen years

Q —And THE JOURNAL about the same time? A —No sir longer on THE JOURNAL because as assistant to the editor I began taking control of THE JOURNAL somewhat longer ago than that

Q —And who was President of the Medical Association when you began with it? A —The Medical Association elects a new president elect every year, but the presidents change every year and I would have difficulty in remembering exactly who was president each year, but I can give you a list of many of the presidents

Q —I asked you the question who was the President when you started with the Medical Association, and if you don't know, say so? A —I don't remember exactly, that year

Q —When was Dr Simmons President? A —Dr Simmons was never President

Q —What was his connection? A —Dr Simmons was editor and general manager of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and of the work of the association

Q —What Simmons is that? A —George H Simmons

Q —He, I believe, had been an advertising doctor? A —I don't know

Q —Well, you have seen many of his advertisements, haven't you? A —No, sir

Mr Harrell —I object to this line of testimony; I don't see where it has any place in this case Dr Simmons is not on trial here, and it has nothing to do with this case

THE COURT —This is cross examination, and it was brought out by you on direct examination that ordinarily ethical doctors don't advertise, and they can test him out on that if they want to

Q —You have read this book, "Medical Mussolini" A —I have seen it, yes, sir

Q —You have noticed the advertisements on page 22? A —I have noticed what purports to be an advertisement

Q —You don't deny those are copies of Dr Simmons' advertisements? A —I merely state that purports to be a copy That is the only one I have seen

Q —You don't deny those are some of the advertisements of Dr Simmons? A —I don't know of my own knowledge

Q —You do find it in a published book? A —Yes, sir

Q —And, by the way, Doctor, you wrote a book and advertised it, Doctor, a book of home remedies, you wrote a book yourself and advertised that in the Chicago *Tribune*, didn't you? A —No, sir

Q —You didn't? A —No, sir

Q —Didn't you publish a book? A —I wrote a book, but I didn't publish or advertise it

Q —You mean to say there wasn't an advertisement in the Chicago papers A —There may have been advertisements, but I didn't pay for or issue the advertisements

Q —You know there was an advertisement for the sales for "Home Remedies" in the Chicago papers? A —Not for "Home Remedies"

Q —You know there was considerable furor and criticism among some of the American Medical Association doctors about that very episode? A —There was some excitement, yes, sir

Q —Now, Doctor, when you wrote that article about Dr Brinkley you say you had never met him? A —I had never met him to my knowledge, no, sir

Q —Do you know whether he had gone to the same school you went to? A —I never to my knowledge went to any school that he went to

Q —Do you know whether he did—you don't know that, whether he did or didn't? A —To which school do you refer?

Q —Either one of the schools that you went to? A —To my knowledge he never at any time was enrolled as a pupil in the University of Chicago or the Rush Medical College

Q —Do you know whether you had ever had opportunity to meet him and know him before you wrote this article? A —I don't know that I had ever had any opportunity to meet him, certainly not to my seeking

Q —You are quite positive you had not, so far as you know, had any opportunity to meet him? A —No opportunity of my seeking

Q —I didn't ask you that, I asked if you know whether you have ever been thrown in the same place he was? A —I wouldn't know of it. I don't know

Q —You know that just a few months before you wrote this article you came over on the boat from Europe, on the same boat with him and had quarters on the same deck, I mean the same floor of the boat? A —As far as I know there was no opportunity for me to meet Dr. Brinkley on the boat

Q —So far as you know? A —Yes, sir

Q —Isn't it true that Dr Brinkley made an effort to meet you, and you were out on the deck and you were sitting there reading a book and he walked around in front of you and you looked up and then you dodged back in the book and refused to recognize him or know him or meet him? A —The question was did I have opportunity to meet him, and the answer is I didn't have any opportunity to my knowledge to meet Dr Brinkley

Q —That is not the question A —Define the word "meet"

Q —I asked if he and Mrs Brinkley didn't come around to where you were sitting in a chair reading, and you refused to look up and notice him? A —To my knowledge on one occasion he walked by the place.

Q —Answer the question

THE COURT —I think he was answering it

A —I am answering the question directly and completely

Mr Morriss Sr —I asked didn't he walk by, and I asked that he answer it yes or no

THE COURT —I think he is answering the question and you stopped him

Mr Morriss Sr —I asked him to answer it yes or no, and I have that right to have him answer it that way

THE COURT —I don't think so, I think some questions can be explained

Mr Morriss Sr —Well, he can explain it later

THE COURT —I don't think you can fairly conduct that examination in that way

Mr Morriss Sr —I will ask it in another way

Q —Did they walk in front of you and stop in front of you as if to meet you? A —They walked in front of me, but I don't recollect that they stopped

Q —You don't recollect? A —That they stopped

Q —Who are they? A —Dr and Mrs Brinkley

Q —Do you know it was them? A —Yes, sir

Q —You did? A —Yes, sir

Q —You knew they were on the boat? A —Yes, sir

Q —You were on the boat, then, with them, how many days? A —I think slightly over four days

Q —And did you know that your daughter, who was on the boat, had been playing games with Mr Brown, the witness who testified, did you learn that at the time? A —At the time my daughter stated to me that while she was practicing golf in the golf net—

Q —I am not asking what she told you A —My only information is what she told

Q —Answer this question yes or no Did you learn they were playing together? A —My daughter said to me—

Q —Answer the question yes or no Did you know they were playing together? A —My daughter didn't say they were playing together

Q —Answer the question—

THE COURT —He said his daughter—

Mr Morriss Sr —I asked him to answer the question yes or no There is no need for the witness to be stubborn in answering the question yes or no, and I have that right to that answer

A —If the question is "did I learn they were playing together," then the answer is "no"

Q —Did you learn she had met him or had been associated with him on the boat? A —I learned that he had approached her

Q —Did you learn that there had been anything more than just his approaching her? A —Some conversation

Q —Some conversation? A —Yes, sir

Q —On her part or his? A —*Apparently mostly on his*

Q —Apparently mostly on his? A —Yes, sir

Q —Did you learn at the same time that he—or at a later day on the boat—that he was a tutor of Dr Brinkley's son? A —I learned that

Q —You did? A —Yes, sir, I did

Q —Then did you learn that Dr Brinkley's son had been playing games with her, with your daughter? A —I didn't

Q —With the boy, I mean, your boy? A —I did not

Q —Did you learn that Dr Brinkley's son was on the boat? A —I did

Q —You did know that Dr Brinkley *and his family and the tutor were* on the boat, did you? A —I did

Q —And how many days did you say you were on the boat with him? A —Slightly over four days

Q —Was there another instance when you met them face to face and turned back and turned away? A —Possibly on the day when the boat was docking

Q —Was there another instance after you got off of the boat when you came upon them and turned and went away? A —I believe at the Hotel Waldorf

Q —So, you didn't only not seek him, but you avoided him and evaded any opportunity to meet them or any opportunity for them to meet you? A —Yes, sir

Q —You had years previously published in one of these magazines an article about the doctor? A —Yes, sir

Q —And that was an article similar in many respects to the present article, wasn't it? A —Yes, sir

Q —And then you had published in January 1938 the article, I mean the publication mentioned, of Dr Brinkley, hadn't you? A —*Yes, sir*

Q —This was what you told your counsel was a part of a series of articles, wasn't it? A —Yes, sir

Q —Under the large caption "Modern Medical Charlatans"? A —Yes, sir

Q —Now, in January of *1938*, you published this about Dr Brinkley "In the obscure Kansas village of Milford, a blatant quack, one John R Brinkley, whose professional record reeks with charlatanism of the crudest type, has for some years been demonstrating the commercial possibilities of goat gland grafting for alleged sexual rejuvenation," didn't you? A —Yes, sir

Q —In that article you inveighed against those beliefs and practices that you oppose, is that right? A —Yes, sir

Q —Among other things, you stated in that article this, did you not "*The chronic invalid, weak, despairing, eager for comfort responds more* readily to the laying on of hands"? A —Yes, sir

Q —"As a result, there are legends in every religious history not only of healing but of raising from the dead by such procedures In ancient days, men were not sufficiently familiar with the scientific tests of death to ascertain with certainty that people in a comatose state were not actually dead but living It is quite possible for the hysteric to imitate the signs of death It is also quite possible for the power of suggestion to cause such a hysteric to discontinue the symptoms and apparently to rise from the dead," you published that, too, didn't you? A —Yes, sir

Q —In order words, among other things, that was a part of your belief, wasn't it? A —Yes, sir

Q —And then, in the February issue you hadn't had any word from Doctor about your January issue, had you, when you published the February issue? A —Not that I know of

Q —Then you published in the February issue this account, which has been read to the jury, is that right? A —Yes, sir

Q —Do you remember when you wrote it? A —I wrote the article, I believe, in the previous September or October or possibly November, I would have to verify my records on that

Q —When was it after you got back off the boat trip? A —I reached my office about the second week in September; the article was written to read before the Chicago Literary Club in November

Q —We are not asking about that, and *don't go off on irresponsive* matters that you know necessarily extends this record You got back about the middle of September, is that right, from the boat? A —In my office about the first week of September, I believe

Q —Then, it was a few days later that you began writing this article? A —Much later.

Q —How much later? A —I believe about the third or fourth week in October

Q —Just within a few weeks after you got back, at any rate, you began writing these articles about Dr Brinkley? A —Yes, sir Not about Dr Brinkley but about modern charlatans

Q —He is in there? A —He is included

Q —You began writing about Dr. Brinkley a few weeks after you got back off of the boat, A —Six or seven

Q —You had had some days to discuss with Dr Brinkley his methods, had you wanted to? A —Had I wanted to, yes, sir

Q —Had you ever come to Del Rio in the years from 1933 to 1938 to get first hand information and first hand knowledge of Dr Brinkley's operations and practices and hospital? A —No, sir

Q —You had never made any investigation at all? A —Personally, no

Q —Had you ever made any request of him for information? A —Personally, no

Q —In other words, you had never even been to Del Rio before you wrote this article? A —No, sir

Q —Never made any effort to contact Dr Brinkley? A —Personally, no, sir

Q —You had never made any effort to learn of him about his practice and his operations or his reasons for it, or anything about that, had you? A —I made no *personal effort*

Q.—Did you ever consult any of these doctors who had worked for him and operated with him here—did you ever consult Dr. Petermeyer? A —No, sir He is an osteopath

Q —Did you ever consult Dr Petermeyer? A —No, sir.

Q —Dr Davis, did you ever consult *him*? A —*No*, sir

Q —Did you ever consult Dr. Osburn? A —No, sir.

Q —Dr. Conn? A —No sir

Q —Dr. Harris? A —No, sir

Q —Dr Kline? A —No, sir

Q —You said Dr Petermeyer was an osteopath? A —Yes, sir

Q —You referred to him on the stand yesterday as "Mister," instead of "Doctor"? A —Yes sir

Q —You don't recognize him even as a doctor? A —I, personally, do *not*

Q —And you say you never wrote a letter to any of these men, never interviewed them, never made any effort to interrogate them or learn anything from them about Doctor? A —Not that I know of

Q —Tell us whether you did? A —I don't remember that I did

Q —If you did, you would remember, and would you tell us whether or not, in your best judgment, you made any direct effort to ascertain any facts from any of those men? A —No, sir

Q —Nor from Doctor? A —No, sir

Q —Nor any employee or nurse of his hospital? A —Not personally

Q —You say not *personally*, but did you send somebody here to Del Rio to ascertain about him? A —Various investigations have been made

Q —I didn't ask you that A —If I personally sent—no

Q —Did you personally *have anybody come* to Del Rio to make any investigation about it? A —No, sir

Q —And did you ever ask an opportunity to witness one of these many operations that have been shown that he performed here on people? A —No, sir

Q —And you told us yesterday that the information you got, so far as any patient was concerned, was a second hand report about some one patient who had gone to Mayo? A —That had to do with financial matters not the operation

Q —That is the only patient you contacted, wasn't it? A —Personally?

Q —Yes, sir A —Yes sir

Q —So you never made any inquiry from any patient whether he was satisfied or helped or benefited or cured or injured, did you? A —Some of the patients wrote to me

Q —*I am* asking you if you made any personal contact with or any investigation of any patient? A —No sir

Q —You didn't make any effort to, did you? A —Personally?

Q —Yes, sir A —No, sir

Q —And did you have anybody make any investigation here in Del Rio about what he was doing in reference to the literature that he was sending or receiving or the letters he was sending or receiving, did you send anybody to Del Rio for that purpose? A —Personally?

Q —Yes, sir A —No, sir

Q —*You didn't do it* yourself or have anybody do it, did you? A —Not personally

Q —And, yet, in this article you charge him with being the arch quack of all quacks, the arch charlatan and charging him with using the mails to defraud didn't you? A —All investigations—

Q —Answer the question yes or no A —All investigations—

Q —Answer my question You charged him with that, didn't you? Answer that question yes or no A —I charged him with that yes, sir

Q —Without any character of investigation? A —No, sir, that is not true

Q —Do you disclaim malice? A —Yes, sir

Q —You disclaim it, do you? A —Yes sir

Q —You just had the very kindliest feeling for him, didn't you? A —I had no feeling for him at all, one way or the other

Q —Why did you decline the opportunity time after time— A —In some twenty six years of investigations of charlatans, I have never met personally or sought the acquaintance of any charlatan

Q —In other words, you are now asserting to this jury that he is a charlatan, in your opinion, is that right? A —Yes, sir

Q —And in your answer you alleged the truth of the publication? A —Yes, sir

Q —On the stand you are claiming the truth of the publication, aren't you? A —Yes, sir

Q —Now, are you in any way committed by any authority, governmental or other authority with the power to say who may practice medicine in the United States and who may not? A —No, sir

Q —You are not? A —No, sir

Q —Do you set yourself up to? A —No, sir

Q —When did you first read this article which charged you—the book which charged you with attempting to be the Mussolini of Medicine in America? A —I read that about, I think, the first time a month ago maybe

Q —And shortly before that there was great *controversy* and furor in the medical profession about a good many of your methods wasn't there? A —No sir

Q —Hadn't there been a great deal of dissension about it so much so that you have had some trouble up at Washington lately that is due to some of your practices? A —No, sir

Q —I am going to ask the question, and I don't want you to answer it until counsel makes the objection You were recently indicted in the Federal Court in Washington, and you are under indictment now? A —*Yes, sir*

Q —And that was due to your methods, what the many doctors called your high handed methods in dealing with and trying to control the medical profession? A —No, sir

Q —You disclaim that? A —Yes, sir

Q —The indictment was against yourself and the *Medical Association* for violation of the anti trust laws, wasn't it? A —No, sir

Q —What was it? A —The indictment involved twenty physicians practicing in the District of Columbia, and five employees of the American Medical Association, there was no indictment of the Association as such

Q —What about you? A —I was one of the five employees of the Association

Q —You were indicted? A —Yes, sir.

Q —And what was that indictment for, against you? A —The indictment had to do with the fact that *certain hospitals* in the District of Columbia—

Q —Answer the question, what was the charge made?

THE COURT —He was answering the question I very much doubt the admissibility of this line of evidence, anyhow

Mr Morriss Sr —I gave counsel opportunity to object

THE COURT —He didn't object because he didn't mind it, but from the Court's standpoint the evidence is inadmissible, I think it is prejudical and if any objection was made I would sustain it

Mr Morriss Sr —I gave *him* the opportunity.

THE COURT —You give opportunity to object to all questions *that are* improper We can't try the case in Washington

Mr Morriss Sr —I realize that, but—

THE COURT —I think you better discontinue this line of testimony

Mr Morriss Sr—My thought was only with *reference* to his activities

THE COURT —He is not being tried in regard to that I have no doubt that he has his side of that thing in Washington Gentlemen of the Jury, you will disregard all of that with regard to this indictment, it has *nothing* to do with this case and is a collateral issue, and you have no business to try to try it out, and you must discard it *from* your mind and I mean for the jury to do that, because otherwise I owe it to Dr Fishbein the duty of letting him explain his side of it to you, the imputation has been cast, and I have no doubt that he has a side, but it *isn't material and you are not* interested in it, so you will not discuss that matter in regard to the indictment or refer to it or *carry* it in your minds, just discard it from your minds

Q.—What I want to bring out, Doctor, is that there is existing an element of opposition and rebellion against your methods in the American Medical Association, is there not? *A.*—The only way I would have of knowing that would be a breaking off of some part of the membership; as I explained yesterday the membership has increased by 8,000, and no one of those said to be in rebellion has resigned.

Q.—And, yet, there are many, many thousands of physicians throughout the United States who have been members in the past and who are not now? *A.*—No, sir.

Q.—You don't mean to say there are many thousands? *A.*—No, sir, cerainly not.

Q.—On the first of January 1938, after you had written and before you had published this article, there w[illegible] 50,000 physicians in the United States that were not [illegible] Association, weren't they? *A.*—No, sir, not [illegible] licensed to practice or in practice? I can give you the exact figures.

Q.—Physicians licensed to practice? *A.*—165,000 physicians in the United States licensed to practice.

Q.—And you said yesterday there were 111,000 members now? *A.*—Yes, sir.

Q.—But there were 8,000 less the year before? *A.*—No, sir; that was in June 1937.

Q.—So, there are approximately 50,000 licensed physicians not members of the Association? *A.*—Yes, sir.

Q.—And you know that at one time Dr. Brinkley was a member of the Medical Association, don't you? *A.*—I haven't personally investigated that point, so I wouldn't want to say yes or no.

Q.—Do you attempt to deny that Dr. Brinkley was for some years? *A.*—I don't attempt to deny it, I merely say I do not know of my personal knowledge.

Q.—You told us yesterday of the investigation, rigid rules and investigation as to qualifications to become a member? *A.*—Yes, sir.

Q.—Then, if Dr. Brinkley was a member for some years, then, that investigation had been made of him and he had been passed, hadn't he? *A.*—I would have to verify that, and, I can verify it if you wish, by telegram.

Q.—I am asking if Doctor had been a member for some years, why, he had passed that investigation and been approved? *A.*—If he had been, why, he had, yes, sir, probably.

Q.—Now, do you not know it was only after his experimentation and his operations and his work in the attempted use of glands that the medical profession raised a furor and he was expelled from the Association? *A.*—I don't know that of my personal knowledge.

Q.—Well, you would know it from the information because you were there, connected with the American Medical Association, weren't you? *A.*—I don't keep in my mind the personal lives of the entire 111,000.

Q.—Then, you wrote this article charging Doctor with being a quack and unqualified and so forth, without looking up to know whether he had even been a member for years of the American Medical Association, or not? *A.*—For every statement made in the article, I had—

Q.—Just a moment, please, just answer the question, and don't argue the matter with me, just answer the question. *A.*—What is the question?

Q.—You wrote that article without any investigation to see whether for years he had been a member of the Medical Association, or not? *A.*—That information I didn't have before me.

Q.—And you didn't look it up? *A.*—I did not.

Q.—And, now, with reference to the matter of Doctor having been earnestly seeking to put his new ideas and his new experiments in medical—his new research and the results of it to the medical profession —you told us that when a man has a new idea that he thinks is beneficial he tries to give it to the public, is that right? *A.*—He submits it to scientific periodicals.

Q.—Doesn't he give it to doctors and call them in, noted doctors? *A.*—Yes, sir.

Q.—You did know he had, among his early operations, called Dr. Nesselrode? *A.*—Yes, sir.

Q.—He had called Dr. Nesselrode in to witness the operation, hadn't he invited him in, and you learned from the doctor that he had been invited in to witness the operation? *A.*—He invited him in connection with the revocation of the license, that is all I know.

Q.—Didn't he invite him to witness the operation? *A.*—In connection with the revocation of the license.

Q.—That is the qualification you are putting on it now? *A.*—That has always been the qualification.

Q.—Did you say anything about that a while ago? *A.*—Yes, sir.

Q.—You testified in answer to that to your counsel? *A.*—Yes, sir.

Q.—You testified that it was in connection with some matter of investigation or in revoking the license? *A.*—Yes, sir.

Q.—You had already told that, had you? *A.*—Yes, sir.

Q.—At any rate, you know that when the matter was questioned why, then, at least, at that time, if not before, he invited that doctor in to witness his operation? *A.*—Yes, sir.

Q.—You do, as a matter of fact, from common report, know that he called many doctors in to witness the operation, don't you? *A.*—I do not.

Q.—You know he traveled far and near to perform the operation and demonstrate it to the public and doctors? *A.*—No, sir.

Q.—Did you know from information that he performed it in many places? *A.*—No, sir.

Q.—Or various places? *A.*—No, sir.

Q.—You don't know about that? *A.*—No, sir.

Q.—You didn't consult Doctor before you wrote this article to learn whether or not it was his earnest desire to help ailing humanity when he did that experimentation? *A.*—I heard him say that on the radio.

Q.—You didn't consult him about it to find out anything about his views on it? *A.*—No, sir.

Q.—With reference to the operations that he performs now in the main, which is this prostate operation, you never wrote him nor questioned him nor interviewed him to find out his views, his own personal views about the benefit and the need of that, did you? *A.*—No, sir.

Q.—Nor the good of it, and you have told us as to those operations —and neither did you talk to any patients of his? *A.*—No, sir.

Q.—Are you prepared to say, then, you never witnessed that operation? *A.*—I never witnessed the operation.

Q.—Either by him or anybody else? *A.*—No one else does it, I believe.

Q.—You don't deny that many doctors perform that operation that he performs now days, do you? *A.*—I don't know of any doctor who transplants goat glands.

Q.—I didn't ask you that. *A.*—That is what the article says.

Q.—In the article you say he discontinued that? *A.*—Yes, sir.

Q.—You knew at the time he discontinued that operation years before? *A.*—Yes, sir.

Q.—All right, now, I am talking about the operation that he principally performs now on sick men, the prostate operation? *A.*—Which prostate operation?

Q.—The prostate operation which you heard Dr. Petermeyer describe. *A.*—May I ask if you refer to the operation involving the injection of mercurochrome or the prostatic resection by the introduction of the tube into the urethra?

Q.—I refer to both, but primarily the first. *A.*—I know few, if any, doctors who practice the operation that involves cutting the vas or tube and injecting mercurochrome.

Q.—Don't you know that doctors throughout Texas are doing that operation? *A.*—I don't know of any well recognized urologist who does that operation.

Q.—Do you know any of the doctors of San Antonio? *A.*—I know quite a few doctors in San Antonio.

Q.—Do you know whether any of the doctors in this region, any doctor in this region performs that operation? *A.*—In Del Rio?

Q.—Yes, sir. *A.*—I know very little about the operations done in Del Rio in general.

Q.—In other words, you don't know, then, whether doctors who have had the best opportunity to investigate and to see and talk with patients and learn the results, and so forth, have gone to performing that operation or not, do you? *A.*—Will you restate the question?

Q.—In other words, you don't know, then, whether doctors who have had the best opportunity to investigate and see and talk with the patients and learn the results, and so forth, have gone to performing that operation or not, do you? *A.*—That is a complicated question. In general, I know very little about whom the patients of Dr. Brinkley have gone to next.

Q.—Do you know anything—have you read anything, I will put it, in the medical journals about this type of operation? *A.*—I have read about various types of operations on the vas.

Q.—Now, then, do you not know that the second operation where, as Dr. Petermeyer said, the condition is so bad as to preclude the probable benefit by the first operation, that is, the urethral operation, that is commonly performed by many doctors all over the country, isn't it? *A.*—I didn't understand from Dr. Brinkley's broadcasts that he performed that operation.

Q.—I didn't ask you that. *A.*—You mean the operations performed by Dr. Petermeyer?

Q.—You heard Dr. Petermeyer describe Dr. Brinkley's operation by the urethral method? *A.*—You mean the resection operation—that is a very common operation.

Q.—That is a very common operation where they have a very bad condition? *A.*—It is an operation for the enlargement of the prostate, and that is surgical.

Q.—That is what they call the second operation? *A.*—That is a surgical operation.

Q.—That is the second operation? *A.*—I don't know what he calls it, but it is called a surgical operation.

Q.—If the condition is bad, but not absolutely desperate, they try that operation, don't they, that is, the urethral method, isn't that true? *A.*—That operation is performed for simple enlargements of the prostate without any evidence of a malignancy.

Q.—Then, the only thing they can do, if that can't cure them, is remove the gland entirely? *A.*—By surgery.

Q.—Remove the gland? *A.*—Yes, sir.

Q.—And they couldn't very well remove it without surgery? *A.*—The doctor states he doesn't do any surgery on the prostate, and it occurs to me that that is very radical surgery.

Q.—Do you know of any method by which anybody could remove it without surgery? *A.*—No, sir, and that is the reason I was surprised to hear it.

Q.—I am asking about the entire removal. *A.*—That is surgery.

Q.—That is the last and desperate operation? *A.*—It is not too desperate.

Q.—That is the last operation? *A.*—It is a difficult operation.

Q.—That formerly was the only method, that is, in any recent years, up until the last decade or so, that was the only operation? *A.*—Surgical removal was the adopted operation until the development of the transurethral prostate resection.

Q.—That involves the cutting away of a considerable portion of the prostate? *A.*—Yes, sir.

Q.—I mean of the gland. *A.*—Yes, sir.

Q.—And that is by a process of going up there with the instruments and cutting it away and taking it out? *A.*—Just slight portions are removed at times, yes, sir.

Q.—And have you ever performed that operation? *A.*—No, sir.

Q.—Have you ever performed an operation of the removal of the prostate entirely? *A.*—No, sir.

Q.—Have you ever performed or attempted to perform this operation, what Doctor calls his technic? *A.*—He has so many technics, but if you refer to the injection of the mercurochrome in the vas, I have not.

Q.—He has many? *A.*—He seems to have many technics.

Q.—You heard Doctor testify, Dr. Petermeyer and him both, as to the name of the operation that he calls the new technic? *A.*—Dr. Petermeyer called it—he said it used to be called one thing, and now it is called the surgical technic.

Q.—Have you ever performed that operation? *A.*—No, sir.

Q.—Have you ever witnessed it? *A.*—The injection of the mercurochrome in the vas?

Q.—I asked if you ever witnessed that operation? *A.*—No, sir.

Q.—Are you meaning now to say that all they do is inject mercurochrome, is that the meaning you want to convey to the jury? *A.*—I merely wish to convey to the jury that I merely understood Dr. Petermeyer to describe several technics, and among those technics there was the injection, the cutting of the vas and the injection of mercurochrome; and that seemed to be one.

Q.—Did you learn from Dr. Petermeyer, or gather from him, that that was all he did, just cut the vas? *A.*—There were many combinations; apparently Dr. Petermeyer was wishing to say they do various combinations of all of these technics.

Q.—Didn't he tell about the ligation there, and all of that? *A.*—No physician—

Q.—Answer the question. *A.*—No. You do not seem to understand the surgical technic.

Q.—Didn't he say he didn't cut but tie? *A.*—Sometimes they cut and sometimes they tie.

Q.—The ligation is tying? *A.*—Yes, sir.

Q.—And he told you they don't ordinarily cut but tie them off? *A.*—I think the evidence shows what he testified.

Q.—Are you trying to convey that you have the impression that he only just opened and put in the mercurocrome, and that is all? *A.*—Certainly not, and I didn't say that.

Q —Are you trying to minimize or belittle the operation when you speak about the method of injecting mercurochrome? A —I wouldn't minimize any attacks on the human body of that type

Q —What do you mean by attack on the body A —Any opening of the human body is referred to sometimes as an attack on the body

Q —Are you trying to convey the idea that in your opinion that operation is not beneficial? A —In my opinion there is no evidence scientifically collected and established that that operation is beneficial

Q —And, yet, while the evidence shows that he has operated on many thousands of people for that, you never talked to one of them, is that right? A —The patients?

Q —Yes, sir A —His patients?

Q —Yes sir—and you say you never performed it or seen it performed and you never talked to a man that had it performed on him, have you? A —No, sir May I correct that? One man I did see who had that operation performed on him by another surgeon, and I would like to correct that statement in that manner He just came to my mind

Q —How did you know it was the same operation? A —The man described it to me, described to me the operation he had performed upon him by this surgeon

Q —The man himself described it? A —Yes, sir

Q —The surgeon didn't? A —No sir

Q —Now, Doctor, you say you did publish and offer for sale a family doctor book? A —No sir

Q —Telling people how to treat themselves at home? A —No sir

Q —Do you have a copy of that book with you? A —No, sir, I don't carry it with me

Q —Do you have it? A —Yes, sir, but I don't carry it

Q —What is it? A —"Modern Home Medical Adviser"

Q —And how long ago was it gotten out? A —It was gotten out approximately four years ago, four or five years ago

Q —That was for home use? A —That was a book of advice

Q —Was it for home use? A —Yes sir

Q —And you don't deny that the book was advertised in the Chicago *Tribune* do you? A —It is now advertised in many newspapers in the United States

Q —You don't deny it was advertised in the Chicago *Tribune*? A —The ads in the *Tribune* were small

Q —Do you deny it was advertised in the Chicago *Tribune*? A —I don't recollect any advertisements in the Chicago *Tribune* until the last two weeks

Q —Do you deny it was advertised in the Chicago *Tribune*? A —Recently?

Q —I have asked you seven or eight times if you deny it was advertised in the Chicago *Tribune* A —No sir

Q —Don't you know it was? A —Yes, sir

Q —Don't you know that the complaints piled in from doctors about your advertising the book? A —No, sir

Q —You don't know that? A —I know there were complaints, but they didn't pile in

Q —They didn't pile in? A —No, sir

Q —But the members of your association complained about the advertisements of your book? A —I think a total of six members

Q —Six members? A —Yes, sir

Q —How about the other practitioners who weren't members, how about that was there some of them? A —I don't know

Q —Now, what does it cost a year for a doctor to be a member of the Medical Association? A —*Eight dollars in the American Medical* Association for Fellowship in the Association, and in each county and state society the dues vary according to the county and the state society

Q —I asked about the American Medical Association A —To become a Fellow of the American Medical Association a member pays his $8 and subscribes for THE JOURNAL, and that is included in the $8

Q —There are many sources of income which the American Medical Association has besides the mere matter of the doctors' dues and fees? A —Outside of THE JOURNAL it is all outgo, there is nothing else coming in and it is all expenditure

Q —You have THE JOURNAL and the *Hygeia*? A —Everything else loses money except THE JOURNAL

Q —I didn't ask you that A —You said income—net income or gross

Q —I am asking about the income? A —Gross income from subscriptions?

Q —What is the subscription to the *Hygeia* per year? A —It varies as to whether one subscriber takes it for one year or two years or five years or in groups from $1 25 a year up to $3

Q —What is one person a year? A —One person a year is $3

Q —And it carries advertisements all of the time? A —Yes, sir

Q —Many advertisements of all sorts? A —Not enough

Q —In other words, it sells space to advertisers? A —Yes, sir

Q —And in addition to that, you spoke of the 125,000 subscribers, and do you admit there are that many? A —Yes, sir

Q —And in addition to that it sells on all of the newsstands, practically, of account, doesn't it? A —No, sir

Q —It doesn't? A —Not on all by far It sells on approximately a thousand newsstands

Q —Does it sell on newsstands in all of the large cities? A —On some, probably.

Q —You heard the testimony that it sold at several different places? A —I can tell you how many copies are sold on the newsstands

Q —You heard the testimony that it was sold and carried in several different places on the newsstands in Del Rio, you heard that? A —Yes, sir

Q —And would that be true generally of a town the size of Del Rio? A —Yes, sir, all towns of approximately this size, I imagine, at least one newsstand would have the magazine

Q —And it is sold by news butchers on the train and is always carried by them on the trains? A —No, sir, not that I know of

Q —You won't say that it isn't? A —I never say it on the train, and I don't know that our circulation department has made such an arrangement

Q —Is there any state in the union where it does not sell? A —No, sir; it sells in practically every state

Q —You said you could tell us how many copies are issued for general sale aside from the subscriptions? A —The newsstands sale would approximate about 2,000 copies or more per month

Q —And the magazine is subscribed to by most of the doctors, isn't it—by many doctors? A —No, sir.

Q —By many doctors? A —Seventeen thousand

Q —Seventeen thousand doctors? A —Yes sir

Q —Now, those magazines are left in their waiting rooms for their patients to read A —The doctors complain that the patients take them away

Q —They are put on the table to read? A —Yes, sir.

Q —And, of course, you couldn't estimate—you have no way of estimating how many persons read the one magazine, we will say, just the one copy? A —I wouldn't know

Q —You would say that generally speaking quite a number of persons read each magazine, would you not? A —I hope so

Q —You would think so? A —Yes, sir

Q —Especially where it is left in a doctor's office? A —Yes, sir

Q —And patients call day by day? A —Yes, sir

Q —And they are left there many months? A —Yes, sir

Q —And many people throughout the United States have an opportunity to read that article? A.—Yes sir

Q —And that paper? A —Yes, sir

Q —And that magazine? A —Yes, sir

THE COURT —We will take our mid morning recess, gentlemen

At this time a recess was taken, after which the following proceedings were had, in the presence of the jury

Questions by Mr. Morriss Sr.:

Q —Doctor, concerning the circulation of the *Hygeia*, do you not make periodic reports to the authorities as to the amount of circulation? A —Yes sir

Q —Do you remember when the last one was made? A —We make a report each year to the House of Delegates

Q —Do you remember when the last one—I am talking about the governmental authorities? A —No, sir, no report is made on circulation to any governmental authority

Q —You make no report on circulation to state authorities? A —No sir

Q —Not to the federal agencies? A —No, sir

Q —But you made it to whom? A —The House of Delegates of the American Medical Association

Q —Do you remember when you made it last? A —One was made last June in San Francisco, and another is about ready to be made now

Q —Do you remember what the reports showed last June in San Francisco? A —Exactly how much loss was sustained during the year?

Q —I am not asking that. How many copies of *Hygeia* were published? A —I believe approximately 125,000 monthly

Q —Is that as near as you can give it to us? A —Yes, sir I am not directly in charge of circulation

Q —But as editor and as having been editor all of the years, you do not know? A —Approximately

Q —You don't know exactly? A —No, sir

Q —That was subscribers? A —I don't know exactly

Q —I say there was that many subscribers? A —No, sir; I believe the number of copies issued, and that would be separated from the subscribers

Q —You don't know how many number of subscribers—if you don't know, why, say so? A —I don't know exactly

Q —You said something yesterday about your having heard Dr Brinkley on the radio offering some pills for a bill or a dollar, or something of that kind, you say you heard that? A —I heard him offer a solution in a broadcast asking people to send him a bill, and not—

Q —I didn't ask you that A —I am repeating the testimony.

Q —I say, didn't you hear him offer a bottle of pills for a dollar? A —I never said a bottle of pills

Q —You said in your article, you spoke about a bottle of *pills that* he sold over the radio? A —The article stated, I believe, the word "pill"

Q —I believe it did A —Yes, sir

Q —Your counsel didn't ask you about that Whom did you get that information from, that he sells pills over the radio? A —I had before me the accumulated material from the Bureau of Investigation

Q —That is your answer as to why you made that statement? A —I probably made the statement for that reason I might have had some material of that sort

Q —I am asking you if that is the best excuse you can give to that statement? A —I don't conceive of it as an excuse

Q —I am asking you if that is the best excuse for publishing that? A —I don't conceive of it as an excuse

Q —I didn't ask you that? A —Yes you did

THE COURT —The way you frame the question the witness is not going to answer it without an argument

Q —You have no justification for that save and except you had before you some material of some sort? A —And that I heard him on the radio relative to a solution

Q —And as to a solution? A —Yes, sir

Q —And that is all you have on that? A —Yes, sir

Q —When was it, by the way, that you heard him, claim you heard him on the radio and heard him speak of the solution bottle? A —Some years ago

Q —How long ago? A —I would say approximately four or five years ago, but I wouldn't be sure exactly

Q —Where from? A —I believe from the station in Mexico

Q —The station here? A —In Mexico

Q —That is the best that you can give us on that, is it? A —Yes sir.

Q —Doctor, you spoke about these hospitals that are investigated and so forth, and did you not know that the Brinkley Hospital in Milford, Kansas, was for several years a member of the American Hospitals in good standing? A —I did not

Q —The American Hospital Association? A —I did not

Q —Do you deny it? A —I can't deny it if I didn't know it

Q —You just don't know whether that is true or not? A —That is right

Q —You told us yesterday that what the requirements are for a hospital to be a member, that is to say, they are investigated by investigators, and they are investigated before they become members of the American Hospital Association? A —I didn't make that statement

Q —What is the statement about the investigation before they become a member? A —I referred only to the investigation made by the Council on Medical Education and Hospitals by the American Medical Association, it having to do with two lists, a list of acceptable hospitals or registered hospitals and a list of hospitals approved for interns

Q —But, at any rate, they are investigated before they become members? A —Before they are registered by the American Medical Association

Q —Doctor, do you know it to be historically true that the medical profession has always been very slow to accept innovations, do you know that? A —Historically true?

Q —Yes, sir A —Some innovations, and others very promptly

Q —Say, for instance when Wise discovered the childbed fever A —You refer not to Wise but to Semmelweis

Q.—Yes, sir. There was great opposition against it a long time? *A.*—The discovery was made simultaneously by Oliver Wendell Holmes in this country, it was suggested by Holmes in this country, and by Semmelweis, and neither submitted proof but merely made the suggestion, and until the proof was established the medical profession delayed the acceptance of the concept.

Q.—Didn't they run him out of the country? *A.*—Who do you mean by they?

Q.—The medical profession. *A.*—Of this country?

Q.—Where he was. *A.*—Where was he?

Q.—If you know? *A.*—I know the life of Semmelweis, and he wasn't, to use good language, he wasn't forced out of the country in which he was, but he departed.

Q.—He departed? *A.*—Yes, sir.

Q.—Because of the furor raised among the doctors for what he claimed? *A.*—Because of his inability to gain acceptance of his concepts.

Q.—I wonder if you know whether Harvey's circulation of the blood, when he discovered it, was accepted very readily? *A.*—The medical profession of his time, which was approximately 311 years ago, failed to accept his theory until it had been established by him by evidence.

Q.—Until he had established it? *A.*—The burden is always on the innovator to establish his concepts.

Q.—Don't you know generations went by and condemned him very bitterly? *A.*—I didn't know that.

Q.—You didn't know that? *A.*—No, sir.

Q.—What about the vaccinations, were they slow to accept that, or did the medical profession accept it readily? *A.*—I didn't conceive of vaccination as a theory. When Edward Jenner established vaccination, he first made the statement based on the study of a dairy maid—

Q.—I am asking you was it accepted readily or slowly? *A.*—You seem to ask for history, and I am giving the history to you.

Q.—I am asking if it was accepted readily.

THE COURT:—If you are going into that line of examination the Doctor is entitled to make his explanation; but I doubt the pertinency; it is, of course, very interesting and it is of interest to me and I am sure the jury, but you can't compress it down into any narrow limits, and if you ask those questions you have to let him answer it in his own words.

Mr. Morriss Sr.:—I think the question is apparently in reference to innovations, which the doctor here has, and the question of their acceptance.

THE COURT:—That is a matter of argument. If you want to go into it I will let you, and there is nobody objecting to it, and I won't object to it, but if you ask the questions you will have to let him answer.

Q.—Jenner's vaccination against smallpox was very slow in acceptance? *A.*—Not for those times, but it would be slow now.

Q.—Pasteur's dog vaccine for hydrophobia, that was slow in acceptance? *A.*—Not for those times.

Q.—He was very seriously condemned about the fool theory? *A.*—By some physicians.

Q.—And the tuberculosis bacilli, that was by Koch, wasn't it? *A.*—Yes, sir, the discovery by Koch of the germ of tuberculosis.

Q.—And they condemned him for a long time for that? *A.*—No, sir.

Q.—They didn't? *A.*—No, sir.

Q.—Is it true or not that the medical profession has appeared to be slow to accept and disposed to condemn any new thing or innovation in medicine? *A.*—Within the last twenty years the medical profession has accepted almost immediately insulin for diabetes, liver extract for pernicious anemia; the prostate operation is accepted by scientific urology. I would say that they accept them nowadays too rapidly; so rapidly, in fact, that the government has passed a law, and asked them not to be too rapid, and has tests for the drugs before they are accepted, and that applies to therapeutic devices and foods.

Q.—Have you noticed throughout the history of the medical profession that they were rather slow and critical of innovations? *A.*—They never accept without evidence.

Q.—And they have bitterly condemned for some generations many—or for many years, many innovations that proved to be of great benefit to mankind? *A.*—I can't answer the question without the definition of the word "they."

Q.—The medical profession, many members of the medical profession, the body of the medical profession, the body of the members of the medical profession? *A.*—I would say in general the statement is not fair.

Q.—You would say that as to those various things I asked you about? *A.*—You haven't been quite fair.

Q.—I haven't been fair, is that it? *A.*—Yes, sir.

Q.—And wherein, then, have I not been fair in asking you the questions? *A.*—The nature of the question was such as to attempt to throw disrepute upon the medical profession for their delay in accepting new announcements of discoveries until the investigator or introducer of the discovery had established by scientific evidence the real worth of his proposed innovation or technic.

Q.—That is your argument on that matter, is it? *A.*—That is no argument, it is a simple statement of truth.

Q.—Do you deny now that Dr. Brinkley is licensed today in at least four states to practice medicine? *A.*—To my knowledge he is licensed at present in Texas and Arkansas, and his license was revoked in Connecticut.

Q.—I didn't ask you anything about that, whether his license was revoked.

Mr. Morriss Sr.:—This witness, I think, has mentioned that perhaps fifty times in his testimony here, but wholly without being asked about that, and I will ask the Court to instruct the witness to answer my question.

THE COURT:—I think there is evidence in regard to the matter. The way you frame your questions, Counsel, invites an argument; instead of asking a question you say "Do you deny that," and that is a signal of combat immediately; you ask for an argument in the way you frame the question.

Q.—I will ask you, yes or no, if you deny that today he is licensed in Tennessee?

THE COURT:—You can't require him to answer yes or no every time.

Q.—Do you deny he is today licensed to practice medicine in the state of Tennessee? *A.* I don't know about Tennesse.

Q.—Do you know whether he is licensed in the state of Missouri today? *A.*—I don't know.

Q.—So, you can't deny that Dr. Brinkley today has licenses to practice medicine in as many as four states of the union? *A.*—I know he is licensed in Arkansas and Texas, and I do not know of any other licenses.

Q.—Do you know whether he was ever licensed in Tennessee? *A.*—I don't know.

Q.—Do you know whether he was ever licensed in Missouri? *A.*—I could not tell you without verifying it, but I can verify it.

REDIRECT EXAMINATION

By Mr. Harrell:

Q.—Now, Doctor, regarding meeting Dr. Brinkley on the *Normandie* on this return trip from Europe in 1937, will you tell us what reason, if any, you had, that is, when you saw Dr. Brinkley, for not pursuing him and making his acquaintance? *A.*—In the first place, I had never been introduced to Dr. Brinkley by any one in whom I would have confidence; and, frankly, because of my position I am constantly sought by many people and I must find out the nature and character of the people before I make their acquaintance, and, in the second place, having recognized Dr. Brinkley from his pictures, primarily, I remembered that at various times Dr. Brinkley had brought suit against me and against the American Medical Association and against various other publications for various amounts of money, and I didn't conceive that it would be the proper part for me to perform in order to seek out the acquaintance of any one who had at various times brought suit against me and against the American Medical Association and various publications for damages and for other reasons.

Q.—Now, Doctor, regarding your medical practice and study, will you tell us—I don't believe it was brought out—if you attended any clinics during the period of time since you graduated from medical school? *A.*—My position is such that I am constantly visiting all the important clinics and hospitals of the United States in order to obtain at first hand information concerning any discoveries which seem to be of importance and well established in the field of medicine; I visit the Mayo Clinic at least once each year, making rounds with Dr. Will Mayo and seeing patients and operations; within the past three weeks I visited the New York Hospital, where I saw Dr. Du Bois and Dr. Cattell in an investigation having to do with the detection of pain associated with surgical procedures; I have visited within the past year, and every year, at least four or five leading hospitals and institutions of research such as the Rockefeller Institute, the Nelson Morris Institute, recently the Cincinnati General Hospital where I learned at first hand about the use of nicotinic acid in pellagra, and sulfapyridine in the treatment of pneumonia; I have frequently seen operations on prostate glands performed by surgeons of repute who were members of the American Urological Association.

Q.—Doctor, there is some mention made here of a certain book this morning, "Medical Mussolini," and do you know anything about this book? *A.*—Well, I have characterized the book as a scandalous work, and the author has published it and circulated it; I may say in advance that I never answer any personal attacks made upon me; I believe my record stands for itself.

Q.—The author of this book is the same Morris A. Bealle who was formerly the editor of a certain magazine entitled *Plain Talk* magazine, is that right? *A.*—Yes, sir.

Q.—Doctor, will you tell us if Dr. Brinkley, to your knowledge, has ever submitted his technic for his operation for reduction of the prostate to recognized medical journals of the United States? *A.*—Not to my knowledge; I could say it has not been printed in any recognized medical journal.

Q.—Now, there is mention made here, Doctor, of a certain book of which you were the author, "Modern Home Medical Adviser," and will you tell us the circumstances under which that book was published and any explanation you have regarding the publicity. *A.*—The publishers asked me to prepare for them a book of advice to the public as to the nature of most diseases and the best methods of preventing such diseases and asked me also to discuss such things as the average family could use in a family chest without any danger of harm to them; not wishing to take the entire responsibility on myself, I asked twenty-six of the leading specialists in the United States, including Dr. Joslin, the leading authority on diabetes, and Dr. Russell Wilder, specialist on vitamins and diet, and including many others, to write articles describing the various diseases of the human body and the best methods of preventing them, and that was prepared by having the men write an article in a scientific manner; and since many weren't capable of writing so that the public could understand, and since it is a part of my accomplishment to rewrite material in a form that the public understands easily, these articles were edited and rewritten and sent to the men for their approval and then published in the book, and then the book was offered for sale in the ordinary book stores. I may say that I write the books and do not sell them and do not advertise them; in ordinary publication one submits a book, after it is written, to the publisher, and the publisher then publishes it and promotes the book. The book has been sold in various ways, and it has been used as a premium with such leading newspapers as the New York *Post* and the Chicago *Times* and the Philadelphia *Record*, and has also been used as a premium by *Colliers' Weekly*; the book has a recognized status in the field of public health education.

Q.—Now, when you said in this article, Doctor, in substance or in exact words, "You send your dollar and you get your pill" with reference to Dr. Brinkley selling this medicine over the radio, or answering these letters, what did you mean by that? *A.*—I may say that in writing an author—

Mr. Morriss Jr.:—We desire to object to that; the language is plain and not ambiguous, and it is not a subject of his testimony as to what he intended by it.

THE COURT:—I think it would be admissible. I will overrule the objection.

Mr. Morriss Jr.:—Note our exception.

Q.—There are certain terms in all languages known as idioms, like "you pays your money and you takes your choice," and this is "you send your dollar and you get your pill," and the word "pill" is used as "remedy"; and that might be used and applied to any sort of figurative language used in that way; and when I testified I stated specifically that I had in mind the solution offered over the radio with the statement that the patient need not describe the symptoms, merely put the name on a piece of paper and send it with a bill, after which the remedy would be sent.

RE-CROSS EXAMINATION

By Mr. Morriss Jr.:

Q.—About your book, did you mean to convey the idea that you weren't responsible for it being advertised, that it was left to the publisher, and you mean to say you didn't get anything out of the sales? *A.*—I derive income from writing; that is my profession.

Q.—From that book? *A.*—Yes, sir.

Q.—You didn't mean to convey that you didn't get any benefit out of it being advertised? *A.*—I don't pay for the advertising or the promoting.

Q.—And you got an income for your writing? *A.*—Yes, sir.

Court then recessed.

TESTIMONY OF A I FOLSOM

Dr. A I Folsom testified that he is a physician, residing in Dallas, Texas, practicing thirty-one years, specializing in urology, a member of various medical societies and of the American Board of Urology The evidence then proceeded

Q—Do you know who Dr Brinkley is, Dr John R Brinkley? *A*—I know him by reputation only

Q—Is he a member of any of those boards or associations which you have mentioned? *A*—Not that I know of I think he is not

Q—Do you know whether or not in the past Dr Brinkley has advertised himself as a goat gland specialist? *A*—He has

Q—Now, Doctor, I will ask you if in your opinion it is physically possible to transplant the testis of a three weeks old goat into the testis of a human and have that goat gland live I—It is not

Mr Morriss Sr—Just a moment We object to that, may it please the court The testimony definitely shows the fact that the doctor has not even performed that operation since 1932 or 1933, and that his work has been in the prostate work prostate gland, ever since that time, and was when this article was written The article itself takes notice of the fact that it wasn't any longer his practice, and the defendant has testified that he understood that and knew that long before he wrote this article, and therefore that is just building up a straw man to try to knock down That has nothing to do with the case We admit of course the fact that the article mentioned the past practice, but we think it has no probative force here and that it would be irrelevant and immaterial and incompetent to establish any issue or defense in this case, and I have stated about the time, it is too remote and shows a practice that—that the doctor himself, the plaintiff, explained how long and why it had been discontinued and we would say too that no predicate has been laid and this witness is not shown to be qualified on that question Unless he has shown himself to be qualified on that matter it would be speculative on his part

THE COURT—I think that the sweep of this article that is declared on here is broad enough to put into issue Dr Brinkley's entire professional activities, and I don't think that it could be fairly limited to just what he has been doing in the last few years, so I will overrule your objection on that ground Now, with regard to the qualification of the witness I think his testimony as to his training and experience is amply sufficient to warrant the court admitting his evidence The weight to be given to it, of course, is to be determined by the jury Overrule the objection

Mr Morriss Sr—Note the exception

Q—Will you answer the question, Doctor, or did you? *A*—I think I did

THE COURT—He answered it could not be done

Q—Now, Doctor, in connection with your practice in the field of urology, have you ever dissected and examined and made a study of human testicles? *A*—I have

Q—Have you—well, upon how many such occasions? *A*—That would be difficult to estimate I taught anatomy for three years and dissected anywhere from twenty to forty bodies every year, and in addition to that during thirty years or more I have been practicing medicine I have operated on many of them It would be rather difficult for me to say just how many

Q—Have you kept up with any literature on the subject regarding the nature and construction of the human testicle? *A*—I have

Q—Now, Doctor, as a result of that will you please explain to the jury why, in your opinion, the goat gland cannot live after transplantation into the human? *A*—The principal reason is because of the fact that the blood supply of the piece of tissue that is transplanted—in other words, the vessels from the patient into whom the piece of tissue is transplanted—does not have a chance or time to form blood vessels into this piece of tissue The testicular tissue is a rather delicate tissue, and for that reason it dies before the blood vessels can make their way into the piece of tissue

Q—What would you say as to the fact that when a pocket is prepared into which the goat gland is inserted, that human blood rushes forth and could then be absorbed into the goat gland, causing it to have a blood supply? *A*—The blood itself which would rush into there as a result of the pocket being prepared is purely a temporary thing, that is simply the hemorrhage incident to the operation The blood supply upon which the piece of testis would have to depend for its living would have to be as a result of the slow, gradual growth of small blood vessels from the testicle into the piece of tissue

Q—Would that rushing forth of the human blood provide a temporary blood supply that would sustain life of the goat gland? *A*—No, it would not The more blood that rushed in there at the time of the operation would rather hinder the thing rather than help it because it would tend to kill it quicker than it would otherwise

Q—Now, Doctor, in your opinion is it possible ever successfully to transplant glands from one animal to another? *A*—It has not been found successful, no, sir

Q—Do you know that it has been found unsuccessful? *A*—It has been found unsuccessful It has been done experimentally many different times, and it has never been found successful

Q—Now, Doctor, for the benefit of all of us here concerned with this, will you explain just briefly and in language that we can understand the construction and operation, in general, of the male genital system *A*—Well, the principal—you want principally the testis and prostate?

Q—Beginning with where the sperm is produced to when it leaves the body *A*—The sperm is produced by the testis or testicle, which is a gland made up of a large number of secreting tubules, little small tubes that are wound in and around each other and in a mass and are held together by a membrane bone outside, which gives the testis its form, and then at the upper end of the testicle these tubules are collected together in a few small tubules, and they pass from the testicle out into a structure known as the epididymis Then there comes off a little duct known as the vas deferens or a little tube known as the vas deferens, and it is through this tube that the sperms which are manufactured in the testicle are carried, through this little tubule in the epididymis, and they are finally carried up this little duct through the groin and into the abdomen, and at the base of the bladder this duct expands, gets a little larger, and then there is a little by pass off into a place known as the seminal vesicles That is a little hollow structure about the size of a little glove finger that is irregularly arranged, and the sperms are stored in this seminal vesicle Then coming off from the seminal vesicles is a much smaller tube known as the duct, and that opens into the floor of the prostate gland, and that is where the semen, which is manufactured in the testicle and transported through the vas deferens and up into the seminal vesicles, is finally delivered into the channel of the urethra The prostate gland itself is a gland structure which is about the size of an average sized English walnut It is made up of five groups of glands or groups of tubules or lobes, the principal ones are the two lateral ones and the middle one, and some textbooks in describing them only describe three, but in some textbooks they are described as five, an anterior and posterior, and this structure, the prostate gland, is a little structure very much like a sponge It has a large number of little cavities in it and the secretion of the prostate is manufactured in the prostate gland

Q—Now, will you tell us just where the prostate gland is located in the body with reference to the seminal vesicles? *A*—The prostate gland lies just in front of the seminal vesicles and it surrounds the beginning of the urethra and at the base of the bladder, and it lies just in front of the rectum

Q—Tell us what the urethra is *A*—A channel through which the urine runs after it leaves the bladder

Q—And it is that same channel through which the sperm leaves the body? *A*—It is

Q—The sperm never passed from the seminal vesicles into the prostate direct? *A*—No, sir

Q—Well, what is the function of the prostate gland, then? *A*—The prostate gland is largely the sexual center It is a very richly supplied gland with nerve endings and it has one of the principal roles in the sexual function In addition to that the secretion of the prostate gland has the power When it comes in contact with the sperms, the sperms are little cells very much like a wiggletail they are quiet, they have no motion as long as they are in the testis or in the seminal vesicle or in the vas, but in sexual intercourse the secretion from the prostate mixes with the sperm from the seminal vesicles and the secretion of the prostate has the power to activate or motivate or make them so they move around They become very active, and that is one of the functions of the prostate gland

Q—Now, Doctor, I will ask you what if anything, is the actual effect on a human of transplanting this goat gland in the manner that has been described? *A*—I don't think it would have any effect at all

Q—Well, by that you mean it would have no functional effect? *A*—No

Q—What would happen to it? *A*—I think it would die

Q—What happens when it dies? *A*—It either is sloughed out immediately, or rather soon after the operation, or if it doesn't do that then it becomes filled with scar tissue, fibrous tissue, and simply becomes a scar in the testis

Q—When it becomes a scar, would that be a hard substance or soft, or what? *A*—Scar tissue is always more or less firm or hard

Q—In other words, it would just leave a little bump there? *A*—That is right

Q—Now, this transplanting of the goat gland, whether accompanied by any other surgical or medical technic or not, would the mere transplanting of that goat gland have any effect, in your opinion, upon an enlarged prostate? *A*—Not a particle

Q—Would it have any effect whatsoever upon reducing high blood pressure? *A*—None at all

Q—Would it have any effect on treatment, or in treating hardening of the arteries? *A*—It would not

Q—Would it have any effect in creating energy in a man? *A*—No I don't think so

Q—Or in curing epilepsy? *A*—No

Q—Locomotor ataxia? *A*—No, sir

Q—Neurasthenia? *A*—No, sir

Q—The insanity of the type known as dementia praecox? *A*—No

Q—Diseases of the stomach? *A*—No

Q—Bowels or kidneys? *A*—No, sir

Q—Well, would it have any effect in relieving constipation? *A*—None at all

Q—Would it have any effect in curing sterility caused by mumps? *A*—None at all

Q—As a matter of fact, Doctor, can sterility caused by mumps be cured in any manner? *A*—No

Q—Why is that? *A*—Because of the fact in mumps the involvement of the testis or testicle is what it is, it is an involvement of the testicle itself It is an inflammatory process that results in the destruction of the testis and it is never regenerated

Q—Now, Doctor, how many types do you urologists recognize of prostatic trouble? How do you classify prostatic disorders? *A*—Well, the infections

Q—What do you call that? *A*—Is one

Q—What is that? *A*—That is prostatitis Enlargement of the prostate, we speak of it medically as hyperplasia or enlargement, as it becomes grossly overgrown and obstructs into the channel through which the urine passes, and in about 20 per cent of the cases of enlargement of the prostate the change is a cancerous change In other words, carcinoma occurs in about one out of five

Q—Doctor, you speak of the large prostate closing the channel through which the urine passes How does that happen, just what does it do? *A*—What does the prostate do?

Q—Yes, to close that channel? *A*—Well, the prostate surrounds the neck of the bladder or beginning of the channel, the beginning of the urethra, and just like a horse collar does a horse's neck, and if you can imagine that you suddenly enlarge the horse collar four or five times you can see the pressure on the horse's neck, it might choke him, and the same thing happens in the urethra, the urethra simply becomes choked off so the urine has difficulty in getting through

Q—Now, Doctor, with regard to these little ducts, little tubes you call them, the efferent ducts between the testicle and the epididymis that lies right on it, say like a finger, as you say? *A*—Yes, sir

Q—How large are those little ducts? *A*—They are very small

Q—Well can you give us any more definite idea? *A*—Well, they are almost microscopic in size You can't see them hardly at all You can feel them, that is, the individual ones

Q—And assume that there are somewhere between twelve and twenty of those, in how confined a space are they located? *A*—In a manner I should say about a quarter of an inch square

Q—Now, Doctor, what does palpate mean? *A*—Feel

Q—Is it physiologically—I will change that Is it possible for you in drawing the testicle out of the enclosure that it is in the scrotum to then feel those little ducts between the testicle and the epididymis? *A*—No at all, you couldn't feel them at all to save your life

Q—Is it possible, in your opinion, to select out any one of those little ducts and tie it off with a piece of linen thread? *A*—It could not be done

Q—Now, Doctor, I will ask you, assume that it could be done and I assume that a man was stated to have prostatic enlargement who was treated in the following manner that a part or all of these little tubes, say half of them, were tied off with linen thread, and that a portion of this other tube leading from there, the larger tube you have described as the vas deferens, may or may not have been taken out and cut away, and assume that the vas deferens is injected with a 2 per cent mercurochrome

solution, and assume that after that operative treatment there is a follow-up postoperative treatment during which approximately six ampules containing 20 cc. of a solution composed of one thousand parts of water to one part of hydrochloric acid and a small amount of blue coloring matter were injected into a man's veins, that covering a period of several days, have you an opinion as to whether or not that procedure might or could in any way affect prostatic enlargement? *A.*—I do have an opinion.

Q.—What is your opinion? *A.*—I don't think it could.

Q.—Will you tell us why? *A.*—Well, that is a pretty big order to tell you why. In the first place, the prostatic hypertrophy does not depend in any way on any change in the testicle itself or in the vas deferens. It is an intrinsic thing, that is, a thing that is inherent in the prostate itself, and I don't think anything that would be done to the testicle or vas would in any way affect the size of the prostate, and I do not think that the solution which you have described could by any remote stretch of your imagination have any effect on it whatever.

Q.—All right. Now, Doctor, have you an opinion—or what would be your opinion as to whether that procedure we have described, we will call it a surgical technic, could have any difference at all, or have any effect at all upon blood pressure? *A.*—None at all, I think.

Q.—Any effect at all upon hardening of the arteries? *A.*—None at all.

Q.—Or upon sexual rejuvenation; improving sexual power? *A.*—None at all.

Q.—Have you ever seen a patient on whom part or all of this procedure had been done? *A.*—Yes, sir.

Q.—And what part of the procedure was done, or was it all done? *A.*—I have seen some patients in whom I was told that they had the compound operation. Now, if that is what—if the questions you have asked me constituted the compound operation, then that is what they have had.

Q.—Well, have you ever seen a patient actually have any part of this operation done? *A.*—Yes. You mean see them have it done?

Q.—Yes. *A.*—No.

Q.—Not even part of it? *A.*—No.

Q.—Did you see those patients before the technic was done? *A.*—I saw some of them before, yes.

Q.—Then did you examine them after it was done? *A.*—I did.

Mr. Morriss Jr.:—We are going to make an objection to anything along this line, because there is no proof at all that they had received the operation from Dr. Brinkley.

Mr. Reynolds:—I withdraw the line of questioning.

THE COURT:—He withdraws the question.

Mr. Morriss Jr.:—We ask all questions with reference to that matter and what questions have gone in be excluded. I don't think he has given any testimony. He said he saw some; he hasn't given any testimony about it.

Q.—All right. Now, Doctor, will you tell us what is the meaning of the word isotonic? *A.*—Isotonic is a chemical term used to represent a solution which is as nearly as possible the same specific gravity and the same structure as the blood stream.

Q.—Now, Doctor, this solution that I have described to you before, a thousand parts of distilled water to one part of hydrochloric acid, with a little blue coloring in it, is that what is known as an isotonic solution? *A.*—No.

Q.—What is it known as? *A.*—I don't know just what you would call it.

Q.—Is it hypo? *A.*—What?

Q.—Is it hypo? *A.*—It is hypotonic.

Q.—What does that mean? *A.*—Below the specific gravity of blood.

Q.—In every day language does that mean weaker? *A.*—Yes, sir.

Q.—Now, then, Doctor, in your opinion what would be the effect of injecting that kind of solution into a man's veins? *A.*—I don't think it would have any effect if it was carefully injected and sterile.

Q.—Would it have any functional effect at all? *A.*—I don't think so.

Q.—Would it have any more effect than distilled water itself? *A.*—I doubt it; I doubt if it would at all.

Q.—Well, is there any reservation on that? *A.*—I don't think it would.

Q.—If there is we want to know. *A.*—No, I don't think it would.

Q.—Is there any point in injecting distilled water into the blood stream or into the veins? *A.*—Not that I know of.

Q.—Is there any point in injecting large amounts of distilled water? *A.*—Well, in surgical practice we frequently inject large quantities, large quantities of that, of an isotonic solution of salt or a glucose solution, that is a recognized—

Q.—I was asking, Doctor, about the distilled water. *A.*—Oh, no; distilled water is considered a bad thing to inject by itself into the blood stream, for the reason that because of the fact that it is a weaker solution it tends to absorb out of the blood cells certain substances which are necessary for their proper functioning, and therefore the distilled water is considered not only not a beneficial but an actively harmful thing.

Q.—Well, now, Doctor, in connection with your general knowledge, not especially confined to the field of urinology, you understand the affliction commonly known of as rickets, do you? *A.*—I do.

Q.—What would you say as to advice to a patient that thyroid extract be used for rickets? *A.*—For rickets?

Q.—Yes. *A.*—There would be no basis for that.

Q.—Well, would there be any good or bad effect, or just purposeless, or what? *A.*—Well, it might be purposeless. On the other hand it might be quite harmful if the patient to whom the thyroid was given was receiving a sufficient supply of thyroid substance from his own gland, then the administration of an excess or an additional amount of thyroid might be definitely harmful.

Q.—Would, in your opinion, would it be good advice to advise a patient to do that without the control and administration of that substance by a physician? *A.*—Thyroid should never be given without a preliminary estimation of the basal metabolism rate, that is, the rate to determine how rapidly the varying functions are going on in the body, which is a qualitative—I mean quantitative—estimate of the amount of thyroid going into the blood stream. If that is low it is given, and if it is not low no thyroid should be given. No thyroid should be given before having that test.

Q.—Would you say a qualified and reputable physician would advise a person to take thyroid extract without designating how, when or where, after merely having been told that a person has rickets, without performing the tests? *A.*—I don't quite get your question.

Q.—Would you say that it is the general custom and practice among qualified and reputable members of the medical profession, after merely having been told by a patient whom he had never seen, that the patient had rickets, that he would then advise the use of some thyroid extract, without indicating how, when, what or under what conditions? *A.*—No, not at all.

Q.—Doctor, do you know Dr. Brinkley's general reputation in the medical profession? *A.*—I do.

Q.—What is that reputation?

Mr. Morriss Jr.:—Now, just a moment. We object to that as not being competent to establish any issue in the case, being improper, irrelevant, immaterial, and not the proper predicate, and not confined to the question; the reputation of any man is the general reputation in the community where he resides and his reputation not among any given body of men or anything of that sort, and we object for the reasons stated.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—Note the exception.

Q.—What is his general reputation among medical men? *A.*—He has a reputation of being a quack.

Q.—What do you mean by that? *A.*—We mean by that a man who practices medicine without regard to the standards, traditional ethical practices and customs of the profession.

Q.—Now, would you say that means merely because he advertises, is that it? *A.*—That is one of the things.

Q.—Is that the only one? *A.*—No.

Q.—What else? *A.*—Because of the fact we think—

Mr. Morriss Jr.:—Just a minute. We object to the testimony because it would call for a conclusion and opinion of the witness, and is not a proper subject of inquiry, not a matter of general reputation.

THE COURT:—This is a case where the man puts his reputation in issue here and says it has been damaged. They have a right to inquire into what his reputation is. Not only inquire as to what it is among doctors, but you can inquire as to what it is among people generally. Overrule the objection.

Q.—Will you answer the question?

Mr. Morriss Jr.:—It isn't a question of his reputation—

THE COURT:—I heard you once on it, counsel. If you want to change the time to what is his reputation in 1938, when the article was published, then I would sustain it to that extent.

Mr. Morriss Jr.:—Note the exception.

Q.—Well, confine the question to prior to February 1938.

THE COURT:—All right.

Q.—Was the advertising that he does the only feature that entered into your statement?

THE COURT:—Let's get that date straightened out as to the reputation before the publication of the article.

Q.—Was he considered by—strike that. Was his general reputation among medical men prior to February 1939 that of a quack? *A.*—It was.

Mr. Morriss Jr.:—Just a moment. We object to that as not being confined to the proper time nor the proper place.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—And it calls for a question which is not properly—

THE COURT:—All right. I overrule the objection.

Mr. Morriss Jr.:—Note the exception.

Q.—Answer the question. *A.*—It was that.

Q.—I will ask you that same question and say in February 1938? *A.*—It was.

Q.—Now, Doctor, will you state what we were trying to get at there, whether or not the advertising is the only thing that entered into that, if you know? *A.*—No, it was not. It was the fact that he was advertising to do a procedure for the relief of a certain condition which everybody who knew anything about the prostatic enlargement knew could have no effect whatever on the condition.

Mr. Morriss Jr.:—Now, we move that that statement be excluded as stating a matter of medical opinion as a matter of his knowledge, and that the question is a conclusion and an improper one and one that he is not qualified to draw and one of course that could only be expressed as a mere matter of opinion.

THE COURT:—Overrule the objection.

Q.—Now, doctor, if I had asked you the same questions regarding his reputation among genital-urinologists, we will say, would your answer be any different? *A.*—No.

Mr. Morriss Jr.:—Just a moment. We make the same objection to that. It is not general reputation. For instance, if the court please, there are many authorities which hold that you may not inquire as to what his reputation is among a part of the community, but it is his general reputation and not his reputation among any particular set and we object for the reasons stated.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—Note the exception.

Q.—Doctor, I will ask you whether or not Dr. Brinkley, either generally in the medical profession or among urinologists, had the reputation of being a specialist in prostate treatments? *A.*—He did not.

Q.—I will ask you whether or not—

Mr. Morriss Sr.:—Of course, we make the same objection to all this, your honor.

Mr. Morriss Jr.:—Is it understood our objection goes to all this in these various forms of questions?

THE COURT:—I don't know, counsel.

Mr. Morriss Jr.:—Well, we do object to the question that has been stated.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—Note the exception.

Q.—Do you know whether or not Dr. Brinkley had any standing in the circles made up of urinologists? *A.*—He did not.

Mr. Morriss Jr.:—Now, just a moment. Don't answer the question, please, sir, until we have an opportunity to object; and we object to that as not any proper—not founded on his general reputation, that the proper predicate has not been laid as to whether he knows his general reputation, and it is merely a conclusion and opinion of the witness.

THE COURT:—Well, counsel, it is necessarily pertinent evidence what doctors generally think of other doctors, if they were in a position to find out about it and know. It would be pertinent to find out what a lawyer was generally thought of by other lawyers or judges, or how architects were regarded by other architects. They are people who are in a better position to know about them than anybody else, and one of the component elements of Dr. Brinkley's damages, if he has been damaged here, would be the lowering of his standing in the opinion of his fellow doctors. If it happens he had no standing in the opinion of his fellow doctors, it follows naturally he hasn't been damaged. So I think the evidence is pertinent and admissible.

Mr. Morriss Sr.:—I want to call attention to the fact that no such allegation as that is made in the petition itself. It is the standing generally.

THE COURT:—Doctors are part of the general public. Doctors refer work to one another, and it is a very valuable asset to a doctor to stand well with other doctors, so I think that is one of the elements that can be considered. I would let him inquire as to his standing with the public generally and I don't think the public generally is in as good a

position to pass on his qualifications as a doctor, but after all it is a question whether his reputation has been injured generally Overrule the objection

Mr Morriss Jr —Note the exception

Q —Doctor, do you know whether or not Dr Brinkley had any standing—and the time is February 1938 or prior thereto—as a genital urinary surgeon?

Mr Morriss Jr —Is it understood those objections go to that?

THE COURT —Yes

The Witness —Shall I answer

THE COURT —Go ahead, Doctor, answer the question *A* —He did not

Q —I ask you, Doctor, whether or not either in the medical profession generally or in the circles of urologists and genital urinary surgeons, Dr Brinkley on that date or before or after at any time had or has the reputation as being the greatest prostatic specialist in the world?

Mr Morriss Jr —Now, just a moment We object to that as not being confined to the proper time The question is duplicitous, asks with reference to several groups, asks with reference to several different times, and it is not confined to the place of residence, and not a competent manner to prove reputation by a question of his standing but it calls for a conclusion and opinion of the witness, and is irrelevant and immaterial, and no predicate has been laid as to his knowledge

THE COURT —I think there is some claim made in that book that he published and gave away that he is the greatest prostate surgeon in the world, is that what it is?

Mr Reynolds —Your honor the reason I asked it at the present time, the evidence yesterday showed night before last he broadcast over the radio a contest for people to write in—it was right here on the stand—they were to write a contest on that phase

THE COURT —Overrule the objection

Mr Morris Jr —Note the exception

Q —Do you remember the question, Doctor? *A* —He did not

The cross examination followed

CROSS EXAMINATION

Questions by Mr Morriss Sr

Q —Doctor, you say you are a member of the American Medical Association? *A* —I am

Q —For how long? *A* —Oh, I have been a member since 1909

Q —Did you know when Dr Brinkley was a member of the American Medical Association or for how long? *A* —No

Mr Reynolds —I object to the form of that question They are assuming he has been a member There is no proof of that

THE COURT —Dr Brinkley testified he had been a member and was put out when he started to advertising

Mr Reynolds —We withdraw the objection

Q —Did you know him when he was a member of the American Medical Association? *A* —I did not

Q —Did you know if he had been? *A* —I did not

Q —Or for how long? *A* —I did not

Q —You didn't know that? *A* —No, sir

Q —In other words, Doctor, the profession, the American Medical Association, those members of the profession who are members of that association decry advertising, don't they? *A* —Well, every reputable—

Q —I am just asking you that question Answer yes or no *A* —No

Q —They don't decry— *A* —I misunderstood your question

Q —I say they decry advertising by a doctor? *A* —Yes, sir

Q —And you don't know whether it was by reason of Doctor's advertising that he either withdrew or was expelled by the American Medical Association or not, you don't know anything about that, do you? *A* —No, sir

Q —Now, Doctor, personally have you performed this operation, the technic of which you spoke about? *A* —I have not

Q —You have never performed it? *A* —No, sir

Q —Have you ever been present at the performance of that operation? *A* —No, sir

Q —You have not? *A* —(No answer)

Q —You have no experience in that operation? *A* —Not in the operation that he described

Q —Yes, sir That is either of their operations, I mean, the last operation he spoke of, nor of the human—or the human or animal gland operation? You never had any experience with either of those, did you? *A* —I have done some experimental work in the transplantation of glands

Q.—Was that human or animal glands? *A* —With dogs

Q —Animal? *A* —Yes, sir

Q —You were never present and saw Dr Brinkley's operation, of either sort, were you? *A* —No, sir

Q —You have never seen nor known personally, had any personal contact or observation of the operation he has performed now for the past number of years on patients? *A* —I have never seen him or his assistants do this operation, no, sir

Q —The prostate gland operation which I would call a minor operation, in other words, not the urethral but the one where counsel have attempted to describe to you the ligating of the tubes and so forth, you never—you have never seen that operation performed by anybody? *A* —No, not for this thing, no

Q —Now, Doctor, there are several stages of the enlargement of the prostate gland, are there not? *A* —Oh, we—

Q —You speak of it in three stages? *A* —Three or four It is variously estimated at three or four

Q —That generally happens at what age in men? *A* —It generally begins to happen in the fifties and gradually increases in the sixties and seventies, *maybe*

Q —Sometimes it happens earlier? *A* —Sometimes it happens earlier, yes, sir

Q —Now, that enlargement, when it gets to what you call the third stage, is likely to entirely cut off the flow of the urine? *A* —The size of the gland apparently doesn't have anything to do with the actual obstruction Sometimes small glands cause much more obstruction

Q —Depending on what gland grows? *A* —No, sir

Q —It has to choke the neck of the bladder, doesn't it? *A* —It has to produce some result which we do not actually and entirely know about

Q —This gland ordinarily and normally in a human being is about how long? *A* —About the size of an English walnut

Q —An English walnut may be large or small? *A* —It is about 5 cm across and about 4 cm deep and about 3 cm thick

Q —Give it to us in inches *A* —An inch and a quarter or an inch and a half across

Q —I asked you that— *A* —About that

Q —That is the question I asked you first *A* —Now, the enlargement, as it becomes diseased or disordered, it becomes larger until it some times gets to what size, maximum? *A* —Oh, I have seen them some times where they are larger than a big grapefruit

Q —Well, would you say four inches? *A* —Four or five or six inches I have seen them that much across

Q —When they get enlarged and diseased that way what is the effect upon the urinary power? *A* —The first effect is obstruction to the passage of the urine from the bladder

Q —What effect does that have in reference to pain and bother, trouble with the patient? *A* —Sometimes it doesn't give them any discomfort or pain at all

Q —Well, as it progresses and gets bad or diseased what are the symptoms of pain they suffer, if you know? *A* —The symptoms of pain?

Q —Yes *A* —I don't know what you mean by that Pain is a symptom

Q —What are the symptoms that are expressed that cause pain what are the symptoms of the trouble or disease that causes the pain? *A* —Pain is a symptom Your question, I don t know how to answer it

Q —What causes the pain, can you understand that? *A* —Yes, sir

Q —Tell us then *A* —Because they can't pass their water

Q —Is that the only reason? *A* —The principal reason, yes, sir

Q —Is it the mere cutting off of the water, is that the only cause of the pain? *A* —That is the principal reason

Q —Well, what others are there? *A* —Infections sometimes, sometimes stones form behind the prostate, sometimes cancer, and there is metastasis that is the cancer going outside the prostate and into the bone of the spine That produces pain There are many causes of pain in the prostate

Q —Now, ordinarily one of the operations is the urethral operation, isn t it, the transurethral? *A* —That is one That is the most recent advance

Q —By that you mean that is just a reaming process up there, you ream out that gland isn't that right? *A* —You go in and actually do a removal of all of the gland

Q —The whole gland? *A* —Yes sir

Q —Well, you mean in the transurethral? *A* —Yes sir

Q —You don't ream it out and remove part of it? *A* —We remove all of it, practically all

Q —Is it commonly done and called the *reaming out process*? *A* —I guess that is what you mean by the prostatic resection

Q —And now do you mean that in every instance of the reaming out process they remove the entire gland? *A* —We try to

Q —You try to? *A* —Yes, sir

Q —Well, would you say you did? *A* —Well, we practically succeed

Q —What is the other method? *A* —The two older methods of removing the prostate gland one was what was known as the suprapubic where the incision is made in the lower part of the abdomen and the bladder is opened and the gland removed through the abdominal wall The other is one in which an incision is made just in front of the rectum, a section is made through to the prostate and the prostate is removed through that direction

Q —Well, both of those contemplate the removal completely of the gland? *A* —Of the gland yes sir

Q —Those both contemplate the complete removal of the gland? *A* —In neither one is there ever a complete removal of the gland There is a portion of compressed gland tissue that is always left *no matter* whether you use the suprapubic or the perineal, where the incision is *made just in front of the rectum*

Q —It is what you commonly call the removal of the gland? *A* —Yes

Q —What are the effects that are likely to flow, what are found to be the effects that commonly flowed from that which you tried to relieve by the *transurethral method*? *A* —What effect?

Q —Yes, what was the bad effect on the patient of that old process of removing the gland? *A* —The bad effect?

Q —Yes *A* —As a rule the results were good They were removed of their obstruction and able to urinate

Q —Could they control it? *A* —Yes

Q —Just the same, as well? *A* —Yes, sir

Q —You mean that in the older days, back we will say a decade or more ago where that was about the only method used, was it not? *A* —Those two methods

Q —All right In many, many instances it was found that it did have a very bad effect in the way of shortening the life of the patient didn't it? Would you admit that? *A* —Well I don't know how to answer your question other than to say this, that in the early days of the operation, of course, the mortality rate in prostatic surgery whether perineal or suprapubic, was rather high but in the last twenty five years that has been reduced to around 4 to 6 per cent *so the good* results in those cases whether done one way or another, amounted to 94 to 96 per cent cure

Q —How long do you say it has been if you know, since the removal of the prostate gland became a practice? *A* —Oh, thirty years

Q —In other words, it has only been within the last thirty years that they learned to do that? *A* —To any great extent, yes sir

Q —Before that do you know what they did? Did they know anything about the enlarged prostate gland? *A* —Before the removal of the gland, as a matter of fact, a hundred years ago a man named Guthrie in England attempted to do what is now being done by the transurethral resection, and prior to that time a Frenchman attempted with another instrument to remove the obstruction through the urethra and some time along in 1870 or 1880 Bottini an Italian attempted to remove the obstruction by a cautery, so the thing extends over a long period of time

Q —But you say the operation hasn't been being performed and removed over about thirty years? *A* —Yes

Q —I am talking about among the American profession what did they do before that for it? *A* —They usually didn't do anything for it or else they put a tube in the bladder above and let the urine drain out that way The patients were allowed to continue to carry that tube the remainder of their lives

Q —Didn't they sometimes practice castration? *A* —That has been used from time immemorial

Q —To try to relieve that trouble? *A* —With no effect

Q —But they practiced that? *A* —Many different efforts were made to do it

Q —Within the past slightly more than a decade the transurethral method has become into rather common use hasn't it? *A* —Yes

Q —And that is recognized as one of the methods isn't it? *A* —It is

Q —It is of course, a rather severe surgical operation, isn t it? *A* —No

Q —It is a surgical operation? *A* —You said a severe one

Q —I am not speaking about mortal but isn't it? Please answer, is it Doctor *A* —It is not unpleasant They have no pain whatever with it

Q —Well, you would say the same thing of any other abdominal operation wouldn't you of any abdominal operation? A —No, I would not

Q —At any rate, if there is a way, if medical science and skill and research can find a way to lighten that operation it would be a great boon to humanity, wouldn't it to perform an easier operation that would cause the patient less loss of time and less likelihood of danger and all that it would be a boon to humanity, wouldn't it? A —Yes, sir

Q —You don't deny that there are the elements of hemorrhage and infection and shock that are in the transurethral operation? A —No sir I do not

Q —You mean you say you don't deny it, or there is none? A —We don t deny it

Q —So of course if that alone could be avoided in an operation where the trouble has not progressed too far, that would be a great boon to suffering humanity, wouldn't it? A —Yes, sir

Q —Now Doctor, when did you first get into the matter of this case? When were you connected in any way with any investigation against Dr Brinkley? A —I haven't been connected with any investigation of Dr Brinkley at all

Q —When were you connected with or talked to first with reference to this case? A —Last Saturday

Q —Last Saturday? A —Yes, sir

Q —In other words, Dr Fishbein had not consulted or seen you with reference to the matter until just last Saturday? A —He didn't see me then

Q —Well somebody did for him? A —If you want to know how—

Q —Was it an investigator? A —No

Q —By some doctor? A —Yes sir

Q —You mean a local doctor up there in your town? A —No sir

Q —By some one else? A —Yes, sir

Q —And by— A —If you want to know, it was by Dr Holman Taylor of Fort Worth

Q —Is he also a member of the American Medical Association? A —Yes sir he is

Q —Do you know anything about his connection in the past with any opposition to Dr Brinkley? A —I do not

Q —You don't know anything about that? A —No

Q —And when did you come down here? A —I came down yesterday morning

Q —From— A —Dallas

Q —From Dallas, at the instance of the defendant? A —Dr Holman Taylor asked me to come down here as a witness in this case

Q —Well did he do that at the instance of the defendant? A —I don't know

Q —You don't know? A —No, sir

Q —You don't know, in other words, whether it was at the instance of Dr Fishbein or of the American Medical Association? A —I do not I don't know where the request originated

Q —Now, you say that you are a member of the American Medical Association I want to ask you do you know whether in cases of this character the members are assessed for expense items or they pay or contribute? A —I don't understand your question

Q —In suits against the American Medical Association or Dr Fishbein do you know whether the American Medical Association, or the members rather are assessed something or charged something? A —No, they are not

Q —Don't you know that—do you remember or did you know about the instance of the publication by Dr Fishbein against Dr Brinkley about ten years ago? A —I don't recall it if I did

Q —You don t remember that Dr Brinkley, then, published an article largely along the same line as this one?

Mr Reynolds —Dr Fishbein

Q —Dr Fishbein I mean, published an article about Dr Brinkley along the same line? A —The one ten years ago I don't remember

Q —Did you know anything about this suit at that time? A —Oh I knew in a general way about it

Q —You knew there was a suit filed against him by Dr Brinkley? A —I have a hazy recollection of it I don't remember any of the details

Q —You remember about the suit having been dismissed by Doctor when he moved off down here, don't you? A —I don't remember

Q —Do you remember whether or not you paid at that time anything made any contribution toward the expense of that suit on the part of the American Medical Association? A —I did not I have never been assessed any special assessment by the American Medical Association

Q —Do you know whether you were requested to? A —No

Q —Were you at that time a member? A —I was

Q —Do you know anything about whether or not all members or what members were asked to contribute at that time? A —I don't think any of them were

Q —You just don't know about that, is that right? A —I don't know

Q —And in this instance, of course, this Dr Hood, you say it was? A —Dr Taylor, Holman Taylor

Q —Dr Taylor having asked you to come, you volunteered to come, didn't you? A —I did

Q —Paid your own expenses? A —Yes

Q —And you weren't of course subpoenaed or under a legal process, but you came down here voluntarily to testify in this case for Dr Fishbein is that right? A —Yes sir

Q —I say at your own expense? A —Yes, sir, I guess it is my own expense so far it is

Q —Well don't you know? A —No, I do not

Q —Well did you— A —The matter has not been discussed with me by anybody

Q —Well did you expect to get your expenses paid? A —I don't expect anything out of it at all

Q —Have you ever talked to any of the patients in this region at all who have been treated or operated on by Dr Brinkley? A —Yes

Q —As to the effect of their operation? Here, that is here, any patient in this county or in any adjoining county, we will say, as to what their condition was and what it has been since Dr Brinkley operated on them? A —I don t think in this county I have had numbers of them from other parts of the state

Q —Have you ever been to talk to anybody in this region? A —This county?

Q —This county or adjoining counties, this district? A —I don't know how big this district is

Q —It takes in the adjoining counties A —Just simply the adjoining counties?

Q —Yes A —The majority of my practice comes from the central and eastern and northern portions of the state I don't think I have talked to anybody from here

Q —Have you ever been down here to Del Rio? A —This is the first time I have ever been to Del Rio

Q —You weren't here during all the time that Dr Brinkley had his hospital here? A —No, I didn't come down

Q —You never saw Dr Brinkley's hospital, either here or in Little Rock? A —No

THE COURT —Counsel, if he has never been here before it necessarily follows he couldn't have seen it

Mr Morriss Sr —I said here or Little Rock

THE COURT —All right

Q —You have never talked to the various doctors who serve his hospital? A —I have never seen one

RE-DIRECT EXAMINATION

Questions by Mr Reynolds

Q —Have you ever been assessed for anything by the American Medical Association? A —No, sir

Q —To your knowledge has there ever been an assessment for any thing? A —No, sir

Q —Any purpose at all? A —No, sir

Q —Who is Dr Holman Taylor, at whose request you say you came down here? A —He is secretary of the Texas State Medical Association

Q —And when and where did you talk to him? A —He called me over long distance telephone last Sunday—I mean last Saturday—and asked me if I would come down here yesterday, and I told him that I would look over my schedule and see if I could rearrange my work and see if I could, and I did, and I phoned him and told him I would

Q —Prior to the time you arrived here had you discussed Dr Brinkley or the method of his operation with any one connected with this lawsuit, lawyers or otherwise? A —You mean this immediate situation?

Q —Yes A —No, sir

Q —Doctor, you say that you never performed this operation which was described to you regarding the cutting off of the small ducts between the testicle and the epididymis Why not? A —Well, I have never seen any indication or reason to I have operated on many testicles and have removed the testicle or the epididymis entirely, or the vas deferens for tuberculosis of the epididymis, but this operation I have never done at all, this particular operation

Q —Have you ever done anything like this for the purpose of reducing the size of the prostate? A —No, sir

Q —Is there the slightest indication, in your opinion, that this opera tion has anything to do with that sort of situation?

THE COURT —I think that has been gone over

Q —Doctor, I would like to ask you if one of these patients that they have mentioned to you came to you and told you that as a result of that operation he told you he had been sexually improved, to what would you attribute that feeling on his part?

THE COURT —I don't know how far you propose to go with that but you may open up a field there that I don t think is proper I don't think individual patients could be brought in here to testify to this and that and the other results

Mr Reynolds —I withdraw that question and all others like it

Mr Morriss Sr —We expect to give counsel the benefit of that We expect to produce many of these patients for the purpose of proving by circumstantial evidence the results obtained by the patient

THE COURT —I will hear you on that later

RE-CROSS EXAMINATION

Questions by Mr Morriss Sr

Q —Doctor, could you before you leave, couldn't you detail to us the symptoms of prostatic trouble in the patient, what the symptoms are?

Mr Reynolds —Just a minute May we ask counsel to confine that to some type of prostatic condition, because all of these various types, the Doctor could talk at great length on them

THE COURT —I haven't found the Doctor very verbose so far

Q —Can you give us what are all of the symptoms of prostatic trouble? A —Prostatic enlargement?

Q —Yes, trouble with the prostate A —There are many different kinds of trouble with the prostate

Q —That is what I want you to do, give us the symptoms of any disease or trouble with the prostate That is, the symptoms the patient feels A —Am I at liberty to choose the type of trouble I describe?

Q —I want you to, as briefly as you can— A —The symptoms of all the prostatic diseases?

Q —All the symptoms that the patient feels in diseases of the prostate A —You are going to be here a long time if you are going to give me that

Mr Reynolds —Your honor, that is the point of my objection If he wants to confine it to prostate enlargement, prostatitis or cancer, that is all right, but the subject he asks covers whole books

Mr Morriss Sr —We don't want it confined

THE COURT —What is the purpose of it?

Mr Morriss Sr —We need to know what this doctor claims are the symptoms of prostatic trouble It is, of course, a matter of proof First, it is quite material if one comes here and says "I have certain—I feel certain symptoms," and if that man then shows the symptoms which are this particular trouble, if this operation is performed and if afterward all those symptoms are relieved through a long period, of course, those are circumstances of a sort to see whether or not he has—whether or not that operation has helped him

THE COURT —It seems to me that if that is admissible it is affirmative proof and not admissible on cross examination They didn't ask him anything about that

At this time the court and counsel conferred

THE COURT —All right

Q —All right, state briefly some of the symptoms, how he suffered? A —Enlargement of the prostate, one of the earliest symptoms is the fact the patient notices he has to get up at night more often than formerly to urinate, two, three, four, five times That gradually increases and he begins to notice he has a loss of force to his stream, he doesn't urinate as freely and forcefully as he did He begins to notice he has some discomfort on urinating, and at the end of urinating and then quite a lot of discomfort, and sometimes the pain will be almost unbear able and they have to be relieved one way or another Those are in brief the main symptoms of enlarged prostate

Q —Is that where the abdomen—in the region of the abdomen? A —Yes, the bladder and lower part of the abdomen

Q —You spoke of—that is the hypertrophy or enlargement? A —That is right

Q —Now, then give us the symptoms of the prostatitis A —That is a much more difficult thing to do Sometimes it is a vague discomfort in the perineum, or what is commonly known as the crotch, in front of the rectum between the rectum and the scrotum, a discomfort discomfort in the groins, low down here and the inner side of the thigh, backaches of various kinds frequency of urination and painful urination and various types of things like that

Q —And, Doctor, those—of course, that condition after some duration or progress may cause a general involvement of the system so far as the strength is concerned? A —When you get into that you get into a tremendous field I would be glad to go into it—

Q —I am just asking you A —Sure, the patient then is a sick individual he becomes uremic, the urine backs up into his kidneys—

Q —I was trying to ask you, it involves a general condition of the patient's health? A —Yes, sir

Q —Weaker? A —Yes, sir

Q —Unable to do his work as usual? A —Yes, sir

Q —And such as that? A —Yes, sir

RE-DIRECT EXAMINATION

Questions by Mr Reynolds:

Q —This last statement made by Mr Morriss involving the general health weakness, inability to do work, isn't it a fact that there are many, many physical conditions to which you would give the same answer that have nothing to do with the prostate? A —Surely

Q —And you wouldn't diagnose prostatic enlargement on the brief explanation of symptoms which you just told about, would you? A —No

Q —There are many, many other things that you have to consider, that have to be confined with it? A —Yes, sir

Q —And you wouldn't diagnose prostatitis from the brief description you gave of it? A —No

Q —There are many, many other things besides that? A —Yes

Q —Tell us some other things that might cause—other than prostatic condition—that might cause the urinary trouble? A —Tumor of the bladder can cause it diverticulum of the bladder That is a pouch off from the bladder wall which holds a large amount of urine ordinarily Inflammation of the bladder, ulceration of the bladder and tuberculosis of the kidney, a stone in the urethra, which is the tube that runs from the kidney to the bladder

Q —That is sufficient In connection with these other conditions a patient might have a backache? A —He might have all of the symptoms we have described except just the difficulty

Q —I would like to know if prostatic enlargement could be connected with or cause in any way epilepsy? A —I don't think so

Q —Dementia praecox? A —No

Q —Hardening of the arteries? A —No

RE-CROSS EXAMINATION

Questions by Mr Morriss Sr.

Q —If you have those different symptoms you speak of that might be caused by different conditions correct and efficient clinical examination, pathology, would disclose whether it is—and, of course, a physical examination would disclose to the experienced surgeon or physician whether he had the prostatic trouble wouldn't it? A —Yes, sir

Witness excused

TESTIMONY OF DR BENJAMIN WEEMS TURNER

Dr Benjamin Weems Turner stated that he had graduated in medicine, that he had served an internship, that he had done postgraduate study and that he is a member of various special societies

The testimony then proceeded

Q —Now, Doctor, you know of John R Brinkley, the plaintiff in this case, do you? A —Yes sir

Q —And for how long would you say you have known of him? A —Well, since the World War, I would say about 1918 or 1919

Q —Well, now, Doctor, during the time that you have known of him have you ever known him to be a member of any of these organizations you have mentioned to which you belong? A —No

Q —Did you know Dr Brinkley—did you know of Dr Brinkley having advertised himself for some time as a goat gland specialist? A —Yes, sir

Mr Morriss Sr —Of course, your honor, the same objection is made to that as to the other witness

THE COURT —Yes Overrule the objection

Q —Now, Doctor, we would like to know your opinion as to whether or not it is physiologically possible to transplant the gland of a goat, the testis of a goat into the testicle of a man by making a pocket in which it is inserted, or in any manner, and have it still live? A —I would say it is not

Q —Why not, Doctor? A —Because there would be no way for nature to anastomose the blood and nerve supply

Q —Now, Doctor, as I understood your answer, it was impossible to anastomose What does that mean? A —Well, for nature to grow together the ends of the vessels and nerves

Q —That is what you meant by that? A —By anastomosis, yes, sir

Q —Why would you say that is impossible? A —Well, for the first reason, that there is no evidence of any of us—no evidence of such ever having been done

Q —Well, suppose we forget that there is no evidence that it has never been done and say from a scientific and medical standpoint just why, or why it wouldn't be possible? A —Well, the minute vessels that supply this tissue, upon removal, are severed and there is no way to unite them Therefore the tissue would die

Q —Well, now, assume that inserting this goat gland into the human gland—an incision is made, from which human blood spurts or comes, anyway, into contact with the goat testicle Would or would not that fact keep the goat testicle alive for any time? A —It would not

Q —Further assume, Doctor, that there was some possible method of providing a blood supply, is there any method of providing a nerve supply? A —No

Q —Well, would the goat gland live in the absence of nerve supply? A —Well, it is possible, I would say

Q —Would it have any functional activity? A —No

Q —Now Doctor, I guess you have answered that there has never been any recorded successful transplantation of any gland of any kind is that right? A —Yes sir

Q —In your opinion, would the transplantation, as we have been talking about here, have any effect, any functional effect whatsoever? A —It would not

Q —Would it have any effect at all upon an enlarged prostate? A —No

Q —Upon prostatic or other types of cancer? A —It would not

Q —Upon sexual rejuvenation? A —It would not

Q —Would it have any effect in treating or curing the type of insanity known as dementia praecox? A —No

Q —High blood pressure? A —No

Q —Hardening of the arteries? A —No

Q —Create energy in a man? A —No

Q —Would the treatment in any way help or cure epilepsy? A —No

Q —Locomotor ataxia? A —No

Q —Neurasthenia? A —No

Q —Diseases of the stomach, bowels or kidneys? A —No

Q —Constipation? A —No

Q —Would it have any effect at all in attempting to cure sterility caused by mumps? A —No

Q —Can sterility caused by mumps be cured? A —It cannot

Q —Why not? A —Because the active function of the organ is destroyed by a sclerosis or fibrous tissue

Q —Now Doctor, as a result of your questions what then would you say would happen to this goat gland? A —I would say it would die and form a foreign body of scar tissue and would probably incapsulate by nature's healing effort

Q —Just leave a hard bump? A —That is all

Q —Is there any process of nature that would lead you to an opinion as to whether that would finally disappear? A —I would think the larger portion would There would be a certain amount of scar that would remain

Q —Now, Doctor, as I understand it in between this space between the testicle and the epididymis, there is contained some twelve to twenty minute tubes that we call efferent ducts is that correct? A —Yes sir

Q —How long are those, generally? A —Well, they are quite small they are barely visible barely detected by the eye

Q —Can you feel them with your fingers? A —No

Q —Would it be humanly possible to separate one of those out and tie a piece of linen thread around it? A —No

Q —Now, I will ask you if tying off all or part of those has ever been—ever been used by you as part of the treatment for prostatic enlargement? A —No

Q —Or by any other man, that is, a urinologist, if you know?

Mr Morriss Sr —Just a minute

THE COURT —By any one he knows, he asked

A —Not to my knowledge

Q —Now, then, Doctor, assume an operation upon an individual who is said to have prostatic enlargement wherein approximately half of these efferent ducts are tied off, wherein a section of the vas deferens the tube leading from the epididymis up into the seminal vesicles may or may not be cut out and removed out, and assume that a 2 per cent mercurochrome solution is injected into the vas deferens that after this operation has been completed, of course, assume that all incisions made are then fixed back together again, sewed up, and postoperative treatment consisting of the intravenous injection of approximately six ampules containing 20 cc each of a substance composed of 1,000 parts of distilled water to one part of hydrochloric acid and also containing a minute amount of blue coloring matter, and that this material is injected into the veins over a period of several days, have you an opinion based upon reasonable medical and surgical certainty, as to whether or not that technic might or could have any effect in relieving prostatic enlargement? A —I would say it would not

Q —Would there be any purpose in your mind to such an operation, medically and scientifically? A —Not to my knowledge

Q —Now, Doctor, would that operation in your opinion have any effect on restoring sexual vitality? A —Not to my knowledge.

Q —In your opinion? A —No, no

Q —And would it have any effect in reducing high blood pressure? A —No

Q —Hardening of the arteries? A —No

Q —Would it tend to create energy in men? A —No

Q —Would it have any effect, in your opinion, on any of these various diseases I named over before? A —No

Q —All right, Doctor, now, would you say that that method was—strike that Doctor, this solution about which I spoke, a thousand parts of distilled to one part of hydrochloric acid and also a minute amount of blue coloring in that, is that type of solution considered an isotonic solution? A —That is hypotonic

Q —Which means what? A —It means less than the concentration level of the blood

Q —It means weaker? A —Weaker

Q —Is there any reason in your opinion why a solution such as that—I will change that question Is there any functional effect in your opinion from injecting a solution such as that into the human veins? A —Well of course, experimentally it was used a number of years back, four or five years ago, but it was discarded as being an inadequate agent

Q —That occasion you are referring to was it or was it not of the same proportion I have given you here? A —No, it was a stronger solution

Q —As a matter of fact, it was about one to five hundred or one to two or three hundred? A —Yes

Q —But never one to a thousand? A —No

Q —Have there ever been any indications even with that concentration that it has an effect of combating infection? A —I think it has been disproved in later years

Q —Incidentally, would an injection of that material have any effect on sexual rejuvenation? A —It would not

Q —Or on any of these other things I have spoken of? A —No

Q —Would it have any effect, injecting distilled water into a person?

A —Not in that dilution

Q —Now, Doctor, do you know Dr John R Brinkley, do you know his general reputation among men, members of the medical profession?

Mr Morriss Sr —The same objection

THE COURT —Why don't you fix the time, counsel?

Q —Do you know the general reputation of Dr John R Brinkley among members of the medical profession in February 1938?

Mr Morriss Jr —Now, we object to that because it isn't confined to the place of the defendant's residence and for all of the reasons stated before May that be understood without our restating that?

THE COURT:—You want to take the same objection you took to it before, the other doctor, Dr. Folsom?

Mr. Morriss Jr.:—Yes, may we have that?

THE COURT:—I will give you that.

Mr. Morriss Jr.:—To all of these questions, unless there is some different line of interrogation, may it be understood that the same objection goes to all of these questions, the same objection goes as was made?

THE COURT:—I understand you are objecting to me allowing them to ask him questions and receive answers with regard to the doctor's general reputation?

Mr. Morriss Jr.:—Yes, sir, and to—well, we think that many of the questions which they asked were not questions of general reputation and no proper foundation.

THE COURT:—I am going to overrule the objection you are making now and let him answer.

Q.—Doctor, the question was his general reputation among members of the medical profession in February 1938. Do you know? *A.*—Well, I don't know just how to answer that question. You mean in regard to—

Q.—As a medical man? *A.*—Well, it was generally not good.

Mr. Morriss Jr.:—The answer was not responsive.

THE COURT:—He wanted to know if you knew his general reputation. If you do, then he will ask you what it is.

A.—Yes.

Q.—Now, what was that general reputation? Don't say "not good," but tell us what it was.

THE COURT:—I think you had better let him answer the question himself.

Mr. Reynolds:—All right, I am sorry.

A.—Well, do you want to put me another question? I mean I don't know just how to answer that.

Q.—Can't you explain to us what you said you knew his general reputation was at that time as a physician and surgeon?

Mr. Morriss Sr.:—Ask if it was good or otherwise, that will be all right.

Q.—If the gentlemen will allow a conclusion, good or bad, then. *A.*—I would say it was bad.

Q.—Do you know his general reputation at that date in circles more particularly confined to urinologists and genital urinologists?

Mr. Morriss Jr.:—The same objection as before. Now, it wouldn't be necessary, and we don't care to interrupt the line of interrogation, if it may be understood we have the same objection which we made to the questions before.

THE COURT:—I think you have indicated, counsel, to the court your objection to this line of procedure. The new rules say all you have to do is to do that to preserve your record. If you want to keep on bobbing up you have the right to do it.

Mr. Morriss Jr.:—We said we didn't want to do it.

THE COURT:—You said you didn't want to do it, but you keep doing it. I think you have a record on that.

Mr. Morriss Jr.:—Well, your honor, if the court will—

THE COURT:—I am not making any agreements with counsel, that is not my province.

Mr. Morriss Jr.:—All we want is that it may be understood that the same objections go, or otherwise it is our opinion, we may be in error, but it is our opinion that in order to properly preserve our record we must object.

THE COURT:—Well, counsel, you had better preserve your record as you want to. I am not objecting to your objecting.

Q.—Doctor, the last question was confined to the same date, but confined also to urinologists and genital urinary surgeons. *A.*—I would say generally unethical or bad.

Q.—What do you mean by unethical? *A.*—Well, there are certain ethics in religions and medicine and ethics are standards by which we are mutually controlled. We call that the ethics.

Q.—Are you referring only to advertising in that connection? *A.*—No, I would say in general.

Q.—Did Dr. Brinkley have a reputation, either among the medical profession or these more confined groups, at that time as being a prostatic specialist?

Mr. Morriss Jr.:—We object to that as leading and suggestive and not being properly confined to the place of the residence and as being confined to a particular group rather than his general reputation, and as being duplicitous as it inquires as to several groups.

THE COURT:—Do you think his reputation would have to be confined to Val Verde County?

Mr. Morriss Jr.:—We think that is the proper test, yes, sir.

THE COURTS—He has testified himself that he has been licensed to practice all over the country and he has issued literature that he has performed operations all over the world and he is known internationally, and I don't think you can tie that down just to Val Verde County.

Mr. Morriss Jr.:—That is our view.

THE COURT:—Overrule the objection.

Mr. Morriss Jr.:—Either that or where he has lived or practiced his profession, in that community.

THE COURT:—He sketched here yesterday that by advertising over the radio he drew patronage from a portion of the country he delineated here that goes up to the Great Lakes and portions of Pennsylvania, and I don't believe you can limit that.

Mr. Morriss Jr.:—We also object also to being confined to a particular portion or group in any given locality and not confined to his general reputation in that respect, but only as among a particular group. You might ask if some member was in bad repute with a club or something like that.

THE COURT:—I don't think that is analogous. Overrule the objection.

Q.—Doctor, the question was if at that time and in those circles, the medical profession generally, he had a reputation of being a prostatic specialist? *A.*—You say did he have?

Q.—That is right, did he have? *A.*—In our association?

Q.—In medical—in the medical profession generally or in the circles confined to urinologists and genito-urinary surgeons, during February 1938? *A.*—No.

Q.—Did he have a reputation of being a genito-urinary surgeon or specialist in that?

Mr. Morriss Jr.:—The same objection to that.

A.—No.

Q.—Did he have the reputation, if you know, of being the greatest prostatic specialist in the world? *A.*—No.

Mr. Morriss Jr.:—The same objection.

Q.—Does he have that reputation now? *A.*—No.

Mr. Morriss Jr.:—Now, we object to the last question as being irrelevant and immaterial to any issue in the case.

THE COURT:—All right.

Mr. Morriss Jr.:—Not confined to the proper time.

CROSS EXAMINATION

Questions by Mr. Morriss Sr.:

Q.—Doctor, you have been practicing in Houston how long? *A.*—Twenty-six years.

Q.—And you have been a member of the American Medical Association how long? *A.*—Twenty-seven years.

Q.—Who asked you to come here, Doctor? *A.*—Who asked me to come?

Q.—Yes. *A.*—The secretary of the State Medical Association of Texas.

Q.—What is his name? *A.*—Holman Taylor.

Q.—In other words, he telephoned you? *A.*—Yes, sir.

Q.—And now, Doctor, you have spoken about the gland operation. What experience have you had in that particular operation, observing it or performing it yourself, that counsel asked you about? *A.*—Well, I haven't done any of the performing of the operations, but I have observed some that have been performed.

Q.—But I am asking you if you have had any particular observation yourself of the operation or in performing it yourself, you have never performed it or been present at it? *A.*—I have not.

Q.—Now, Doctor, there has been a very great advancement in the profession in the past thirty to forty years through all manner of experimentation, has there not? *A.*—Yes.

Q.—You would say that there has been more advancements in the profession of medicine and surgery in the past thirty or forty years than all the history we have record of before, wouldn't you? *A.*—That is very true.

Q.—And, Doctor, they have been doing a great deal of transplanting in late years? For instance, transplanting skin and bone and such as that, haven't they? There has been a great deal of that, and flesh? *A.*—It isn't transplanted, it is grafting.

Q.—Grafting it is the same thing? *A.*—No.

Q.—You cut it off one person or place and transplant it to the other part on the other person and it successfully attaches and grows on there, doesn't it? *A.*—It does in instances in which it is possible to perform.

Q.—That is what I mean, and there has been a vast deal accomplished to the human in that respect, to the human good, in later years, hasn't there doctor? *A.*—There has been no instance of tissue like that being transplanted.

Q.—I am asking you about transplantation. *A.*—Yes, of skin and bone.

Q.—And, Doctor, in reference to the operation—operations for or treatment of the prostate gland, there has been a great advance made throughout the period of the last thirty years in that, hasn't there? *A.*—Yes.

Q.—A little bit back of that time or just behind that time, about the first thing they usually would do was castrate, and that wasn't satisfactory, was it? *A.*—That dates back a hundred years.

Q.—How far back would you say the practice, the common practice, I mean the practice among specialists of that line, the practice of the complete removal of the gland dates back? *A.*—The early fifties.

Q.—Well, it wasn't practiced in our region here with any degree of generality until the last thirty-five or forty years, was it, Doctor? *A.*—Well, fifty, maybe, or sixty or seventy.

Q.—And many, many now perform what is called the transurethric operation, the transurethral operation? *A.*—Yes.

Q.—In severe cases of prostatic trouble? *A.*—Yes.

Q.—Those operations are rather common, aren't they? *A.*—Yes, they are.

Q.—That is where you go through the urethra and you cut away or whittle away—in other words, what is called a reaming operation, isn't it? *A.*—Yes, you might call it that.

Q.—And, of course, when it is bad enough the only way yet is to take it out, isn't it? *A.*—I didn't get that.

Q.—When it is bad enough you can't do it that way, the only method then generally is to take out the entire—that is, the abdominal operation which removes the gland entirely? *A.*—Well, of course, there are a number of methods that are accepted as treatment for prostatic enlargement, and transurethral is only one of three accepted and approved methods. That is limited to a certain group.

Q.—And then the removal, the complete removal by the abdominal process? *A.*—It is impossible to completely remove the prostate by any method.

Q.—You say that you remove all you can get if it is diseased? *A.*—The hypertrophy portion.

Q.—In the transurethral you don't remove it all, do you? *A.*—No.

Q.—Then, Doctor, of course, any method for relief of that very common trouble which would spare the necessity of the operation, even the transurethral, would be a great boon to humanity, wouldn't it? *A.*—It certainly would.

Q.—And, Doctor, any experimentation and finding out a way for human relief, you accomplish it by trying the operations and noting the results, don't you? *A.*—You do.

Q.—And of course if you operate some method upon a large number of persons and you find a very high per cent of satisfactory results, then that is about the best way to know that that operation is successful, isn't it? *A.*—That is the way we all judge ourselves, of course, by statistical data which is compiled by the group.

Q.—Now, Doctor, what is it that causes prostate enlargement? *A.*—That is something that none of us know.

Q.—You just don't know what does cause it, but it is very common, isn't it? *A.*—We think, we have our ideas.

Q.—It is very common, isn't it? *A.*—It is in certain stages of life.

Q.—Well, be more specific, Doctor, what stages? *A.*—Well, the fifties, sixty and seventy years.

Q.—Well, what are your ideas about what causes it? You spoke about your ideas. *A.*—Well, you have to go into the usual accepted principles that are written in our books. It is a tumorous hypertrophy or enlargement or increase in the elements of the prostate in which it grows as a tumor.

Q.—Well, but does that get back to the question of what causes, what causes the growth? *A.*—I don't believe there is anybody that has ever written a positive statement on it.

Q.—I thought you said you had your ideas, aside from whether— *A.*—Well, my idea wouldn't be worth much individually, except what I can prove.

Q.—In other words, you wouldn't be able to express any opinion of your own as to what does cause it? *A.*—Well, it is analogous in life to the change in the female. It is ordained by nature, which we haven't solved. It is the change of life.

Q.—That is your idea of the only cause? *A.*—That is the accepted cause.

Q.—All right. Now, then, Doctor, is that some unbalancing of the male and female sexual hormones which might cause it, is that what it is? *A.*—It isn't all. *It is one of the many hundreds of theories that have been propounded.* It is not an accepted theory.

Q.—You mean there are many hundreds of theories that have been advanced as to what causes it? *A.*—Well, they have in due course of time.

Q.—So it is a matter the profession is largely in the dark about yet, is that it, Doctor? *A.*—*I think that the accepted present status is due* to the so-called change of life in the male.

Q.—*Would that be akin to the unbalancing of the sex hormones in* the male? In other words, the male and female sex hormones in the individual, that is what you mean by that? *A.*—Not necessarily. As I just stated, there is one theory, that is one theory that has been advanced by a certain group of physicians, and hasn't been accepted.

Q.—*You wouldn't say that isn't it? A.*—It never has been proven.

Q.—Now, Doctor, you have been pretty closely connected with the medical associations, the American Medical Association and these other associations, for a good many years? *A.*—Yes.

Q.—I assume you have had business dealings with the association, the American Medical Association? *A.*—Yes.

Q.—And *communication and association in that association with* Dr. Fishbein, known him? *A.*—Yes.

Q.—And, Doctor, you don't know, or did you know, whether Dr. Brinkley was ever a member of the American Medical Association or not? *A.*—Yes, I think he was.

Q.—Do you know how long? *A.*—Well, I never had occasion to check up on it. I think up until some time when he was at Milford, Kansas. *I don't know what the dates were.*

Q.—Well, it was about the time he began radio announcements of his operations, wasn't it? *A.*—Those dates I don't recall.

Q.—Now, Doctor, did you or not have any personal acquaintance with him then or at any time have you ever had any personal acquaintance with him? *A.*—No, sir.

Q.—Have you ever been to his hospital while it was at Milford, Kansas, to go through it or to see anything *about his work? A.*—No.

Q.—It is in evidence that he had his hospital here from 1933 up to last year. Did you ever have occasion to visit *his hospital here? A.*—No.

Q.—Or to talk with him? *A.*—No.

Q.—Or with any of his physicians or nurses or employees of the hospital, *as to the nature of his operation and the work? A.*—No.

Q.—You have, then, no first hand information or knowledge whatsoever about the work or about his operations? *A.*—Oh, yes.

Q.—I say you have no first hand information, all you know is what somebody away who didn't do the work or wasn't present has told you, *is that all? A.*—*Well, the first time that I ever learned of his procedure* was through a group of physicians at Wichita, Kansas, at the *time Dr. Brinkley* was in Milford, Kansas.

Q.—I am talking about you never had any contact with *his hospital or him* or any of his co-operators or anything of that kind? *A.*—No.

Q.—You are a supporter and member of the American Medical Association, you say? *A.*—Yes, sir.

Q.—And of Dr. Fishbein's faction, we might call it, in that organization? *A.*—I didn't know there were any factions.

Q.—Well, you do know that there are many factions, that is to say, there are many controversies inside the medical association about policies and matters of that kind, you know that, don't you? *A.*—Oh, there might be on minor points, *but the general setup, of course, is well* organized.

Q.—Well, you do know that there has also been very considerable discussion and controversy inside the association and out about some of Dr. Fishbein's *operations?* I don't mean physical operations on people, I am talking about his policies, in the last year or so, you know that, don't you? *A.*—I do not.

Q.—You have read about those protests, haven't you? *A.*—I haven't.

Q.—You are acquainted with them? *A.*—No.

Q.—Had you read the book that—

THE COURT:—Counsel, *I think that is entirely collateral matter.*

Mr. Morriss Sr.:—I beg your pardon.

THE COURT:—I think those are collateral matters.

Mr. Morriss Sr.:—Yes, sir, I think it is unnecessary, your honor. That is all

RE-DIRECT EXAMINATION

Questions by Mr. Reynolds:

Q.—You testified here regarding a certain type of operation in which these little ducts were tied off and so forth. In your opinion is that operation, does that operation have anything about it at all that indicates that it could or might be this great boon to humanity that Mr. Morriss asked you about?

Mr. Morriss Jr.:—Just a moment. That question is improper, argumentative, leading and suggestive. We object to it for all those reasons.

THE COURT:—Overrule *the objection.*

Mr. Morriss Jr.:—Note the exception.

Q.—Will you answer the question? *A.*—I would say it could not.

Q.—After hearing about that operation have you yourself any particular desire to pursue its study further?

Mr. Morriss Sr.:—I didn't get *that.*

Mr. Reynolds:—I asked him if he had any desire to pursue that study.

A.—(No answer.)

Q.—Now, Doctor, several things here were said about grafting skin and bone. *Is there any difference between the theories and physical structures underlying the grafting of skin and bone and that of glands* such as the testes? *A.*—It is a very marked difference.

Q.—Will you explain that just in a general way, in common language so we can get an idea of it? *A.*—Well, of course, skin and bone is known as structural nonfunctioning, relatively. Of course, you get out in deep water when you go to describe any of these structures. But the grafting of skin and bone by transplantation, that can be done, but if you attempt to remove an organ you destroy its blood supply and nerve supply, and it is humanly impossible to unite, anastomose or join together these life giving properties which come through the blood supply and nerve supply.

Q.—*Do you know of any recorded case of successfully transplanting* any gland or any organ? *A.*—Not on record.

RE-CROSS EXAMINATION

Questions by Mr. Morriss Sr.:

Q.—Doctor, what about the grafting of the cornea of the eye? *A.*—That is analogous to the skin.

Q.—I say they are doing that? *A.*—Oh, yes.

Q.—Is that skin? *A.*—It is analogous to it.

Q.—What is the cornea composed of? *A.*—It is composed of an epithelium cover. It is analogous to a covering of skin.

Q.—And they do perform the operation very frequently now, removing the eye and operating on it and putting it back, don't they? That is a common operation? *A.*—No.

Mr. Reynolds:—*I object to that.* That has nothing to do with it. It is just prolonging it, whether you pull out an eye and operate on it.

THE COURT:—Just a minute. Maybe he is about through. Is that all, counsel?

Mr. Morriss Sr.:—Yes, sir.

Q.—You know that Dr. Stailey of San Quentin *is a member of the* A. M. A., you know of him and know who he is? *A.*—Yes, sir, the penitentiary physician.

Q.—I will ask you if he hasn't reported *some 10,000 goat gland operations?* A.—No.

Q.—Do you know that? *A.*—He reported some 10,000 vasectomy operations. That has nothing to do with goat glands.

Q.—Just what are the 10,000 operations he speaks of? *A.*—It consists of removing a portion of the vas, which is the tube that carries the sperm from the testicle, and sterilizes the inmates of the *penitentiary.*

Q.—Have you ever attempted or done that operation, Doctor? *A.*—I have.

Q.—And has he done that operation with success, this doctor, is he reported to have done that operation with success? *A.*—Yes, sir.

Q.—*In other words, Doctor, there is a vast amount of experimentation* going on and constantly being carried forward in the interest of medical science, some of which after a time are abandoned and some of which are carried forward successfully, isn't that true? *A.*—Yes, to some degree.

Q.—And in that connection, as you said, the greatest amount of *experimentation* and greatest amount of advancement has come within the past thirty or forty years? *A.*—Yes.

Q.—And now, with reference to that and in recent years, the animal secretions or the secretions of the animal glands have played a very large *part, haven't they? A.*—Gland extracts, *you mean?*

Q.—Yes. For instance, you speak of the thyroid. That has been learned in late years, and you may by reason of the thyroid secretion, that is adding more or less—you learn how to make the stout person thin and the thin person stout by the same medicine, don't you, Doctor? *A.*—*Yes.*

Q.—You have learned that, haven't you, Doctor? *A.*—Yes.

Q.—What is the thyroid gland secretion, what is it they use, what is that, the thyroid medicine, what is it an extract of? *A.*—It is extracts of the thyroid gland dried, desiccated.

Q.—What animal? *A.*—Various animals. *I think mostly Mr. Armour* handles it through his plant.

Q.—What animals, Doctor? *A.*—I don't know for sure.

THE COURT:—What is the relevancy of that?

Mr. Morriss Sr.:—I will just ask this further question.

THE COURT:—I know, but I have been in hopes counsel would turn *loose some time.* I believe you are a long way afield.

Mr. Morriss Sr.:—I will be through with this one *question.*

Q.—The same thing with reference to the sex glands, they have used that a great deal in the last few years, haven't they, and the *hormones? A.*—The thyroid is the only successful gland to date. There are some other glands that have been used.

Q.—Been used by many, many of the very best recognized physicians, too, aren't they, Doctor? *A.*—With limitations, and it depends on which *ones are used.* Some of which have been proved to be no good.

Q.—Yes, but many of them are accepted now and are being used by the best physicians? *A.*—Yes.

RE-DIRECT EXAMINATION

Questions by Mr. Reynolds:

Q.—Doctor, what is it that Dr. Sterling did and was that experimental in any way, or Dr. Stailey, at the penitentiary? *A.*—It was not experi*mental at all,* it was a resection of a portion, of a portion of the vas, which was done by physicians seventy-five years ago and a hundred years ago.

Witness excused.

At this time a short recess was had, at the conclusion of which the following proceedings were had, in the presence of the jury:

TESTIMONY OF JOHN MANNING VENABLE

Dr. John Manning Venable testified as to his qualifications by stating his medical education, including graduate work and his membership in various medical organizations and on hospital staffs. The testimony then proceeded:

Q.—Do you know of John R. Brinkley, Dr. John R. Brinkley, the plaintiff in this case? *A.*—I have heard of him.

Q.—Has he, to your knowledge, ever been a member of any of those organizations you have named? *A.*—No, sir.

Q.—Now, you know Dr. Brinkley used to advertise himself as a goat gland specialist, *do you? A.*—Yes, sir.

Q.—In your opinion, Doctor, is it possible to transplant—

Mr. Morriss Jr.:—Your Honor understands the same objections go to this.

THE COURT:—Yes.

Q.—*In your opinion is it possible to transplant the gland of a goat, the testis into the testis of a man by inserting it in a pocket or by any other method? A.*—No, sir.

Q.—And that is have it still live, I mean to say? *A.*—I understand you, sir.

Q.—Why is that your opinion? *A.*—Because it is unsuitable ground for a graft or *transplanting.*

Q.—*Now, will you explain a little more specifically the fact that it is unsuitable ground. A.*—*Because the place in which it is put in the testicle,* the testicular tissue, is not such to afford adequate blood and nerve supply to a graft to make it live.

Q.—What kind of cells are testicles of goats composed of? *A.*—I beg pardon, sir?

Q.—Of what kind of cells are testicles of goats or the testes of goats composed? *A.*—Epithelial cells.

Q.—Is that the same kind of cells of which human skin is composed? *A.*—No, sir.

Q.—Or human bone? *A.*—Not—no, I wouldn't say it was.

Q.—Now, Doctor, assume that in the transplanting process a pocket is cut into the human testicle and as a result human blood comes into that pocket into which the goat gland has been inserted. Wouldn't that furnish a blood supply to keep the goat gland alive? *A.*—No, sir.

Q.—Why not? *A.*—Because that is blood that is from cut vessels. That is not going to stay in there.

Q.—Would it even furnish temporary life? *A.*—No, sir.

Q.—In transplanting the goat gland in that method is it possible for the goat gland—the goat gland nerves to function? *A.*—No, sir.

Q.—Is there any way in which they can be connected, either—

Mr. Morriss Sr.:—I would suggest that counsel not lead the witness altogether.

THE COURT:—Counsel, inasmuch as this evidence is more or less cumulative, I think it desirable to lead him unless you object seriously.

Mr. Morriss Sr.:—I just wondered if you couldn't avoid leading him.

THE COURT:—I think this is repetition, and I think this is about the last evidence of this kind that the Court will allow.

Mr. Reynolds:—This is the last witness we intend to put on this.

THE COURT:—All right, go ahead.

Q.—Doctor, is there any way that the nerve in the testicle can be attached to the human nerve, either artificially or naturally? *A.*—Please frame that again.

Q.—I am asking if there is either natural or artificial methods whereby the nerve in the testicle of the goat can be connected with the nerve in the testicle of a man? *A.*—No, sir.

Q.—What is it that makes tissue live? *A.*—Nourishment from the blood and nerve supply.

Q.—And it is a fact, isn't it, that the blood has to circulate through the tissue? *A.*—Yes, sir.

Q.—The mere presence of it doesn't help? *A.*—No, sir.

Q.—To your knowledge, Doctor, has there ever been a recorded successful transplantation of any gland from animal to man or man to man? *A.*—No, sir.

Q.—Now, Doctor, in your opinion would the transplantation of this goat gland as described, whether or not accompanied by any other technic, would that transplantation itself, have any effect at all on reducing an enlarged prostate? *A.*—No, sir.

Q.—Would it have any effect upon any of the following diseases or dysfunctions; high blood pressure, hardening of the arteries, impotency, that is sexual inability; would it create energy, have an effect on epilepsy, *locomotor ataxia, constipation, diseases of the stomach, bowels and kidney*, insanity of the type known as dementia praecox, neurasthenia or sterility in man caused by mumps? *A.*—No, sir.

Q.—As a matter of fact, can sterility caused by mumps be cured in any way? *A.*—No, sir.

Q.—And that is because the organ is dead, is that right? *A.*—Yes, sir.

Q.—Would that or not have any effect on cancer? *A.*—No, sir.

Q.—On any type of insanity? *A.*—No, sir.

Q.—What would be the results or effect of the transplanting of that goat gland, what would happen to it? *A.*—Nothing.

Q.—Well, would it just stay there, or what? *A.*—It might be—it would be absorbed, in the event there was no infection it would be absorbed, gradually would become converted into fibrous tissues and be gradually more or less absorbed. There might be a little fibrous tissue left, but not much, where the transplant was placed.

Q.—You said providing there was no infection. Could that gland cause infection? *A.*—Not if it was aseptic technic.

Q.—By that you mean a sterile operation? *A.*—Yes, sir.

Q.—Now, Doctor, regarding the little ducts or tubes between the testicles and the testes and the epididymis that lies along the top of it like a finger, how large are those? *A.*—I would say about the size of a thread or smaller. They vary in size.

Q.—In the ordinary individual can you feel them with your hands? *A.*—No, sir.

Q.—Is it reasonably possible that you can tie off any one of those with a piece of linen thread? *A.*—No, sir.

Q.—Assuming, however, this could be done, would the tying off of part of them in itself have any effect upon an enlarged prostate? *A.*—No, sir.

Q.—What would be the effect of tying off all of them? *A.*—On one side?

Q.—Assume *just one testicle, yes, tie off all those.* *A.*—That side would get no more sperm around it, around to the urethra.

Q.—The same thing as a sterilization operation? *A.*—Yes.

Q.—A sterilization operation, as one is quite commonly done, is done higher up by taking out a section of the vas deferens, is that right? *A.*—Yes, sir.

Q.—Now, Doctor, assume an operation upon a patient who is said to have a prostate enlargement, where half or more of these little ducts on each side are tied off and where a part of the vas may or may not be cut out or removed, where there is an injection of 2 per cent mercurochrome solution into the vas deferens; that after that operation the postoperative treatment included the injection in the vein of a man over a period of several days the contents of 720—six ampules containing about 20 cc., composed of a thousand parts of distilled water to one part of hydrochloric acid and also a minute amount of blue coloring matter, have you an opinion as to whether or not that entire technic might or could have any effect upon an enlarged prostate? *A.*—It would not.

Q.—Is there any indication in any of those steps there that it is directed toward reducing an enlarged prostate? *A.*—No, sir.

Q.—Now, Doctor, this solution of 1,000: 1 distilled water-hydrochloric acid, and a minute amount of blue coloring material, is that what is known as an isotonic solution? *A.*—No, sir.

Q.—It is hypotonic? *A.*—Yes.

Q.—Which means it is much weaker than isotonic? *A.*—Yes, sir.

Q.—As a matter of fact, is there any appreciable difference between that solution and distilled water? *A.*—No, sir.

Q.—Is there any point, therapeutically, that is directed toward the treatment of healing, in your opinion, of injecting a solution of that kind into a man's veins? *A.*—No, sir.

Q.—Would that have, in your opinion, any effect upon restoring sexual vitality? *A.*—No, sir.

Q.—Well, Doctor, I will ask you this question again, now. That operation I described where the ducts were tied off and so on, in your opinion would that operation have any effect on high blood pressure, hardening of the arteries, impotency, epilepsy, locomotor ataxia, constipation, diseases of the stomach, bowels and kidneys, neurasthenia, or any of them? *A.*—This is the injection of this liquid?

Q.—No, it is the whole technic. *A.*—No, it would have no effect.

Q.—Would it have any effect in remedying sterility caused by mumps? *A.*—No, sir.

Q.—As a matter of fact, that sterility caused by mumps cannot be restored at all, can it?

THE COURT:—That has been gone over.

Mr. Reynolds:—I am sorry.

Q.—All right. Now, Doctor, do you know Dr. John R. Brinkley's general reputation among members of the medical profession as a whole in the United States, in February 1938?

Mr. Morriss Sr.:—Just a moment. There is a new objection now. The same objection, by the way, but he says does he know. He can only know that if he knows the medical profession. He said among the medical profession as a whole.

Mr. Reynolds:—Perhaps my language is bad.

THE COURT:—Counsel wants to reframe his question.

Q.—Do you know Dr. Brinkley's general reputation among the members of the medical profession of the United States during February 1938? *A.*—Yes, sir.

Mr. Morriss Jr.:—Just a minute. The same objection to that as heretofore.

THE COURT:—All right, overrule the objection.

Q.—Answer the question yes or no, Doctor. *A.*—I do know it.

Q.—What is that reputation? *A.*—The reputation of making claims that are not substantiated by results.

Q.—Do you know his general reputation among urinologists and genito-urinary surgeons for that same time? *A.*—Yes, sir.

Q.—What is that? *A.*—The same.

Q.—Does he have a reputation among either of those groups, or did he on that date, or does he now, as the greatest prostatic specialist in the world? *A.*—No, sir.

Q.—Does he have a reputation as a prostatic specialist at all? *A.*—No, sir.

Q.—Does he have a reputation of a genito-urinary surgeon at all? *A.*—No, sir.

Q.—Doctor, what in your opinion—no, strike that. Doctor, do you know what in the medical circles and the public generally is usually and customarily and usually understood by the word quack?

Mr. Morriss Jr.:—Now, we object to that, if the Court please, on the ground that what is usually and customarily understood among the medical profession wouldn't govern at all.

THE COURT:—He asked if he knew what was understood by the medical profession and the public generally by the word quack.

Mr. Morriss Jr.:—As we understand it, it is the province of the Court to instruct the jury what quack means.

THE COURT:—What quack means?

Mr. Morriss Jr.:—Yes, sir.

THE COURT:—I don't think so.

Mr. Morriss Jr.:—We have authority for that.

THE COURT:—It may be, but I think the common significance of the word, the idea that it would carry to the public generally, is what governs it. For instance, if I said you were a bum the public generally has an idea what it means. You might get four or five definitions of that from different people, but in the last analysis it is what the public generally and reasonably would think the word meant, the significance that is carried by the word to them. You can go to the dictionaries, I think, and get five or six definitions of the word quack, depending on what dictionary you go to. You could go to the law books and get definitions. You could get different definitions from the doctors. I am subject to correction if you can show me. It is my idea what would the general public get from the language. If you said a doctor was a quack just as if you were speaking of a lawyer if you said a lawyer is a shyster, what would the significance of that be? Ten lawyers might give you ten different definitions of a shyster, but the general public has an idea what it means.

Mr. Morriss Jr.:—Where a term is colloquial and has no established definition I think the Court is incorrect.

THE COURT:—I might be wrong, but I am going to let him testify. I think the public in general and the medical profession think a quack is what they think it is. Go ahead.

A.—What a quack means. A quack is one who presents claims that cannot be substantiated by facts nor results.

Q.—Doctor, in your understanding is it usual and customary for members of the medical profession, if you know, to advertise their remedies and treatments? *A.*—Commercial advertising?

Q.—Yes. *A.*—No, sir.

Q.—You know that Dr. Brinkley does do that? *A.*—Yes, sir.

Q.—Does that in any way enter into your definition of the word quack? *A.*—Not necessarily, no, sir.

CROSS EXAMINATION

Questions by Mr. Morriss Sr.:

Q.—Doctor, who got you to come out here? *A.*—I beg pardon, sir?

Q.—Who got you to come out here? *A.*—The American Medical Association.

RE-DIRECT EXAMINATION

Questions by Mr. Reynolds:

Q.—Did you have any correspondence or instructions or communications of any kind from the American Medical Association? *A.*—No, sir.

Q.—Do you expect to be compensated in any way from the American Medical Association for coming here? *A.*—No, sir.

RE-CROSS EXAMINATION

Questions by Mr. Morriss Sr.:

Q.—Doctor, when did you learn about this matter of this doctor being present to witness the gland operation up in Kansas? *A.*—When did I learn about it?

Q.—Yes. You must have learned about that today, didn't you? *A.*—It was yesterday, sir.

Q.—Whom did you learn that from yesterday, Doctor? *A.*—I saw that in the report from Mr. Harrell.

Q.—Doctor, did you say you just came today at the instance of the American Medical Association? You are coming out here at your own expense, is that right? *A.*—Yes, sir.

Witness Excused.

"THE CHALLENGE OF APPENDICITIS"

A "challenge" is what Reginald Fitz [1] calls appendicitis. His father [2] in 1886 first emphasized in this country the importance of early removal of the inflamed appendix in order to lower the mortality which follows perforation with its resultant peritonitis. In the more than fifty years that has elapsed, the teachings of the earlier Fitz have been abundantly verified and confirmed by countless clinical observations. The way seemed clear to remove the inflamed appendix from our mortality records as a common cause of death, particularly since, with the development of modern surgery, appendectomy in itself is associated with a mortality which is practically nil. Still true today as it was fifty years ago, however, the deaths which occur from acute appendicitis are found only in those patients who have developed a peritonitis from perforation.

The mortality from acute appendicitis has risen sharply during the past few decades. This constitutes the "challenge of appendicitis." The data illustrating this increasing mortality are not difficult to find. The experience of individual states has been particularly striking. For Massachusetts, Fitz [1] presents data which show a sharply increasing mortality curve from 1908 to 1932. He states that, whereas in 1900 only 243 patients died of acute appendicitis, by 1936 it had risen to 490; there was a higher peak in 1930, when the deaths totaled 610. Horsley [3] for the state of Virginia quotes similar statistics; he noted that the death rate from appendicitis rose from 6.4 per hundred thousand in 1913 to 11 in 1930; it was 10.1 in 1935. Startling data have recently been reported by Krech,[4] who points out that in six large American cities the mortality rate from appendicitis has increased in one year from 14.3 per hundred thousand in 1935 to 17 in 1936. In one metropolis the rise was more pronounced, from 14.5 to 23.5 deaths per hundred thousand. These figures are from cities having ample hospital facilities and grade A medical schools; obviously these advantages are not being fully utilized. Hudson [5] has pointed out that, of every twenty children who die, one dies of acute appendicitis. Indeed, the large proportion of the deaths in his disease unfortunately occur in children and young, healthy adults, a factor which makes the challenge even more alarming. In the entire United States more than 16,000 deaths are recorded as produced by appendicitis in 1936; this is a total 50 per cent greater than all deaths due to pregnancy and childbirth in the same period.[4] In several communities the problem has been considered important from the public health point of view and vigorous educational campaigns and propaganda have been instituted in order to educate the public to help meet this challenge.

Education of the public about appendicitis applies to the most important two factors responsible for the increasing mortality, i. e. the increasing use of cathartics for abdominal pain and the delay in the diagnosis and treatment of acute appendicitis. Both factors are associated when any one goes to a drug store for relief from a "belly ache" and indulges in catharsis. This point must be repeatedly emphasized; those with abdominal pain must be warned repeatedly against the dangers of the great American habit of purgation.

Early diagnosis, once the public is educated, lies of course in the hands of the general practitioner. Early diagnosis is not particularly difficult and if followed by prompt appendectomy results in an almost 100 per cent recovery. Unfortunately, this teaching in recent years has received a setback by the resurrection of the 40 year old Ochsner or delayed operative therapy. This swing of the pendulum has been initiated by surgeons; they have done so, however, only as a method of reducing the high mortality in patients past the stage of early diagnosis and who are already suffering from peritonitis. Unfortunately, this teaching, though applied by surgeons to a relatively limited group of patients, has produced in the minds of many physicians a change of attitude toward treatment of all types of acute appendicitis. There has been a tendency to postpone operative therapy in all cases instead of urging appendectomy promptly after the onset of the disease. As expressed by F. A. Coller,[6] "There is one great drawback to advocating any type of delay in the operative treatment of the complications of appendicitis. . . . The bare mention of conservatism in any connection with appendicitis is often misconstrued to mean medical treatment for all appendicitis." A. O. Whipple [7] says "During the past year I have seen four patients . . . with peritonitis" due to appendicitis which the physicians had treated medically because they had "read a good

deal of literature recently about conservative treatment of appendicitis." Birnie [8] finds that this change in point of view has even reached the medical schools; he says "I have been extremely shocked and disturbed at the state of mind of a good many of the interns . . . high-class men . . . [who] seem to think that in all cases of acute appendicitis there are two courses open: you can operate at once or you can use the deferred treatment. . . . Something is radically wrong with the teaching of today if medical students are sent out with the idea that in these cases of appendicitis it is perfectly safe to wait."

From these expressions it seems that there is a growing failure to realize the importance of the old teachings of Fitz.[2] As stated succinctly by William Osler,[9] "There is no medicinal treatment of acute appendicitis." That the situation at present is actually contrary to this teaching is shown for example by Hudson,[5] whose observations are particularly distressing; he found in 100 consecutive admissions for acute appendicitis at the Boston Children's Hospital that only twenty-eight patients were sent to the hospital within twenty-four hours of the onset of pain; significantly all but one recovered rapidly after appendectomy. It was entirely among the remaining seventy-two who entered the hospital more than twenty-four hours after the onset that complications and death occurred. Elman,[10] in a study of peritonitis from ruptured acute appendicitis at the St. Louis Children's Hospital, has emphasized that the delayed operation should be reserved for a small group of patients. In children admitted in good general condition prompt appendectomy is followed by the lowest mortality "whether the appendix is actually ruptured or not." He further emphasizes the difficulty of deciding in many cases whether or not the appendix is ruptured. From the practical point of view this decision in itself is not important.

Reports in surgical literature as reviewed by Ransom [11] do not change but really reinforce the significance of this teaching. The surgeon when he writes of delayed operation in cases of appendicitis refers only to those with peritonitis, cases in which peritonitis should really never have been permitted to develop. The challenge of appendicitis does not concern the treatment in this group; indeed, it concerns the problem of eliminating this group. When all cases of acute appendicitis are recognized early and operation is performed early, no one need die of the results of this disease. Fitz [1] concludes his current paper before the American College of Physicians with this statement:

> Appendicitis, in spite of being a fashionable and well studied disease for more than fifty years, continues to slap our faces insultingly. It is easily recognized. Its treatment, on the whole, is satisfactory, yet it continues to kill each year an unnecessary number of people. May concerted action soon be taken by the American medical profession to meet the challenge of appendicitis and relegate it to the ranks where it belongs: a disease easily diagnosed, of no great danger and, when recognized early and submitted to proper treatment, readily amenable to cure.

ASBESTOSIS

Asbestosis, a definite form of pneumoconiosis, is now generally recognized as an industrial hazard. The first fatal case of asbestosis was apparently described in 1900 by Montague Murray in the Charing Cross Hospital *Gazette*. Cooke's [1] short note in 1924 on the case of a woman dying of asbestosis, and a later paper published in 1927, established asbestosis as a distinct variety of pneumoconiosis.

Asbestos is a fibrous mineral that can be carded, spun and woven. It is a silicate associated most commonly with chrome iron and magnetite. Microscopically asbestos fiber, according to Cooke, is seen to consist of two elements: the bulk of the fiber is translucent and glistening, with here and there black, opaque, angular particles and minute black granules. The dust generated during manufacture consists of these sharp, angular particles and minute granules. Analysis of the dust reveals that the latter are the iron-containing portions of asbestos. These particles, Cooke states, are the "bugbear of the manufacturer, the cause of dust, and a danger to the health of workers in the process of manufacture."

Microscopic sections of the lung in Cooke's case showed an enormous amount of fine granular pigment in the peribronchial fibrous tissue, in the walls of the alveoli, and large, solid, angular particles, which he felt sure were the heavy, brittle, iron-containing fragments of asbestos. McDonald,[2] in his report on the microscopic appearances of pulmonary tissue in Cooke's case, describes peculiar foreign bodies in the alveoli, bronchioles and interstitial fibrotic areas, to which he refers as "asbestosis bodies." Stewart and Haddow,[3] of Leeds and Lynch and Smith [4] of Charleston, S. C., demonstrated asbestosis bodies in the sputum of asbestos workers.

In a recent paper Sayers and Dreessen [5] of the U. S. Public Health Service report the results of an engineering and medical study of the health hazards in the asbestos textile industry in North Carolina. They found pulmonary asbestosis to be the principal physical defect in 541 workers whom they examined. The clinical symptoms included progressive dyspnea, variable cough, substernal chest pain, blood streaked

sputum, decreased chest expansion, emaciation, weakness, clubbed fingers or curved nails. Late in the disease the dyspnea becomes distressing, cyanosis may occur and there may be paroxysms of coughing productive of tenacious sputum. The characteristic roentgenographic appearances of the chest indicate granular or ground glass markings, with more or less obliteration of linear pulmonic markings, localized in the midlung and the bases. Single sputum specimen analysis in each case revealed increased incidence of asbestos bodies with increasing dust exposure. Such bodies were found in the sputum of 46.9 per cent of persons whose condition was diagnosed as asbestosis, whereas 24.3 per cent of normal asbestos-exposed persons had these bodies in the sputum. They were not observed in any of the persons surveyed with less than three months' exposure. The more serious forms of the disease were observed in carders, spinners, weavers, twisters, willowers and pickers. Exposures range from 0.10 to 76 million particles per cubic foot. Thirty-nine persons exposed to the concentration below 2.5 million particles per cubic foot did not have asbestosis. The authors felt that if asbestos dust concentrations in the air are kept below 5 million, new cases of asbestosis will not appear. An engineering study by Page and Bloomfield [6] demonstrated that means are already available for reducing the dust exposure of a majority of asbestos textile workers to less than this amount. The basis of this control is exhaust ventilation near the source of dust.

CARBOHYDRATES AS CONSTITUENTS OF PROTEINS

The first suggestion that carbohydrates may be components of all proteins was made by Claude Bernard, although the basis for this idea was an erroneous interpretation of experimental data. Early in the course of his brilliant studies on the physiology of glycogen, Bernard observed that the feeding of protein to dogs led to an increased deposition of glycogen in the livers of the experimental animals. As this work was done at a time when information regarding either the structure of proteins or the mode of synthesis of sugars in the organism or in the laboratory did not exist, Bernard assumed that the sugar molecule was preformed in the protein and postulated a glucosidic theory of protein structure. However, when the investigations of Lusk and his pupils demonstrated the synthesis of sugar from amino acids, the physiologic basis for the glucosidic structure of proteins disappeared. The presence of carbohydrates in proteins was believed to be limited to a small group of conjugated proteins, the so-called glucoproteins. Despite this view a general lack of agreement prevails as to whether or not the simpler proteins, particularly albumins or globulins, possess carbohydrate constituents. Early sporadic reports of the isolation of carbohydrates or carbohydrate derivatives from the breakdown of proteins were interpreted as indicating an impure starting material contaminated with carbohydrate. Indeed, investigators of protein chemistry frequently used a negative carbohydrate test as a criterion of the purity of their protein preparations.

Within relatively recent times, investigators have reopened the question as to whether carbohydrates may actually be components of the simpler proteins or are present as impurities in the various preparations. The increasing evidence of the important role of carbohydrates in the determination of immunologic specificity has stimulated interest in the possible role of such groups in influencing the antigenic capacity of proteins. Suggestive indication of the presence of carbohydrate in crystalline egg albumin was presented by Fränkel and Jellinek,[1] who confirmed earlier reports of the presence of a polysaccharide in this protein. Considerable interest was added to this investigation because of the identification of mannose among the hydrolytic products of the polysaccharide, thus making available the first definite evidence for the occurrence of this particular monosaccharide in animal tissues. Repetition of this work by other investigators [2] led to essentially confirmatory results, with the conclusion, however, that the carbohydrate is not derived from the egg albumin itself but rather from ovomucoid, present in small amounts. Considerable light was thrown on this controversial subject by the introduction of a colorimetric technic, which led to the quantitative detection of carbohydrates in almost all proteins examined.[3] This striking announcement of the ubiquitous distribution in nature of carbohydrate components of proteins was received with skepticism. Nevertheless, investigations of the composition of various proteins [4] have included reports of the actual isolation of carbohydrate constituents. The carbohydrates that have been identified are mannose, galactose and glucosamine, and the amounts of each of these appear to differ in the various proteins. In some, e. g. certain of the serum proteins, the polysaccharide present has been reported to be composed of units having the composition galactose-mannose-glucosamine, while in other proteins, e. g. egg albumin, only mannose and glucosamine are present. The carbohydrate component of egg albumin was critically examined recently by Neuberger,[5] who demonstrated the integral position of the carbohydrate in egg albumin by a failure to separate the carbohydrate from the protein by denaturation or ultrafiltration. This observation, taken together with the constancy of carbohydrate content on repeated recrystallization of the protein, establishes definitely the firm attachment

between the carbohydrate and the protein. By the use of a newly developed technic, it is reported possible to isolate in almost quantitative yield the carbohydrate group of crystalline egg albumin. The properties of the isolated polysaccharide are described in detail. It is shown to have a molecular weight of about 1,200 and to be composed of four molecules of mannose and two of glucosamine, together with an unidentified nitrogenous constituent.

Although the mode of combination of the carbohydrate with the rest of the molecule remains unexplained, the concept of carbohydrates as constituents of proteins must be considered in connection with theories of protein configuration. The application of similar technic to other proteins may aid in determining to what extent the carbohydrate components of physiologically important proteins determine their immunologic properties and biologic specificity.

Current Comment

A SKIN TEST FOR TOLERANCE TO ALCOHOL

About a year has passed since Nagle [1] proposed an endermic test for tolerance to alcohol. This test, developed in the state psychiatric clinic at Agnew, Calif., consists of an intracutaneous injection of 0.03 cc. of 60 per cent ethyl alcohol (U. S. P.) in the deltoid region with a control injection of the same volume of physiologic solution of sodium chloride in the opposite arm. A wheal about 9 mm. in diameter almost immediately forms, is common in all instances, and has no diagnostic significance. Surrounding the wheal a zone of erythema soon develops, varying in size and intensity in different persons. The maximum reaction is reached by the end of thirty minutes. In about 20 per cent of the 250 patients thus far tested by Nagle the surrounding erythema was of maximum intensity and about 3 inches (38 cm.) in diameter. These persons were classified by Nagle as + + + + intolerant or allergic to ethyl alcohol. At the other end of his arbitrary allergic scale about 10 per cent of his tested group failed to exhibit peripheral erythemic reaction to his arbitrary test dose. These he classified as belonging to the alcohol tolerant or alcohol immune group. Four intermediary groups are recognized on his arbitrary scale. From a study of the personal histories of these patients, supplemented by determinations of the minimum intoxicating dose of ingested alcohol with about fifty volunteers, Nagle concludes that the relative tolerance or susceptibility to ethyl alcohol as determined by the size and intensity of the skin reaction is a direct quantitative index of individual tolerance or susceptibility to ingested alcohol. Volunteers with negative skin reactions, for example, required in the neighborhood of 2½ ounces (75 cc.) of alcohol taken on an empty stomach before showing signs of intoxication. Only one-fourth ounce (7.5 cc.), or a tenth of this amount of ingested alcohol, is sufficient to cause demonstrable speech defects in volunteers whose skin is + + + + allergic to injected alcohol. Skepticism has been expressed by immunologists [2] as to the logical basis for this alleged parallelism. It is interesting to note, however, that the percentage distribution of alcohol tolerance or susceptibility in the general population as determined by the Nagle skin test is approximately the same as the percentage distribution recently reported by German investigators [3] as a result of quantitative blood analyses. Both sets of data show about 20 per cent of the population hypersensitive to alcoholic beverages and about 10 per cent relatively immune.

IMPORTATION OF RADIUM

Only a few hundred grams of radium has been produced since this element was first discovered in pitchblende by Pierre and Marie Curie in 1898. A large proportion has been used for therapeutic purposes. Although radium is also utilized extensively as an activating agent in the preparation of luminous paints and is employed by metallurgists to inspect flaws in metal castings, as much as nine tenths of the radium mined each year finds a use in medicine, particularly for the treatment of cancer. Many hospitals in the United States have accumulated sizable amounts of the metal. Last year it was reported that the combined radium stores of three institutions, Memorial Hospital in New York, Bellevue Hospital in the same city and the State Institute for the Study of Malignant Disease in Buffalo, amounted to almost an ounce. Almost no radium has been produced in the United States since 1923, when richer and larger deposits became productive elsewhere. After that year this country, although it is still the world's largest consumer, has met its needs by importation. In view of this circumstance the amount of radium imported is of interest particularly as it reflects the use of the metal in medicine. The imports of radium into the United States in 1938 established a new high record and the price paid was the lowest ever recorded, according to the Bureau of Foreign and Domestic Commerce.[1] The United States received from foreign countries a total of 598 grains of radium during 1938, compared with 236 grains imported in 1937 and 339 grains in 1934. The value of the imports in 1938 was $787,000, or approximately $1,316 per grain, compared with a valuation of $377,000 for 1937 or $1,600 per grain and $1,082,500 in 1934 or about $3,193 per grain. In 1929 the import invoice value of radium was approximately $3,500 per grain. An important factor in the reduction of the price of radium was the discovery in Canada a few years ago of radium-bearing ore and subsequent exploitation of these deposits. The reduction in price has fortunately made radium more available. Although the field of the use of radium has been invaded by high voltage x-ray machines, the increasing intensity of the struggle against cancer has more than offset any tendency toward substitution; for internal radiation, in particular, radium therapy possesses unique advantages.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Society News.—The Calhoun County Medical Society was recently addressed, among others, by Drs. Howard R. Mahorner and Warren H. J. Hebert, both of New Orleans, on "Appendicitis and Its Complications" and "Strictures of the Rectum" respectively.

Personal.—Dr. George L. Gresham, Andalusia, was recently appointed chief physician at the Speigner State Prison.——Dr. Nathaniel G. Clark, Birmingham, has been appointed chief medical advisory officer of the department of correction and institutions of the state of Alabama, succeeding Dr. Henry G. Camp, Montgomery, resigned.

State Medical Election.—Dr. Mercer S. Davie, Dothan, was elected president of the Medical Association of the State of Alabama at its annual meeting in Montgomery April 20, succeeding Dr. Seale Harris, Birmingham. Other officers include Drs. John S. Tillman, Clio, and John Paul Jones, Camden, vice presidents of the southeastern and southwestern divisions respectively. Dr. Douglas L. Cannon, Montgomery, was reelected secretary. The association will meet in Birmingham in 1940.

CALIFORNIA

Personal.—Dr. Jacob M. Furstman, health officer of the Monrovia district, has been named administrative head of the Pomona health district.——Dr. Stacy R. Mettier, associate professor of medicine, University of California Medical School, San Francisco, is carrying on a six months' study on hematology and the leukemias at Oxford University, London, under the Nuffield Foundation.

Society News.—The San Francisco County Medical Society devoted its meeting May 9 to a panel discussion of peptic ulcer with the following speakers: Drs. William Dock, chairman; LeRoy H. Briggs, Julian M. Wolfsohn, Leo Henry Garland, Emile F. Holman and George K. Rhodes.——Dr. William D. Sansum, Santa Barbara, discussed "The Problem of the Underweight Patient" before the Hollywood Academy of Medicine April 13.——Dr. Hans Lisser, San Francisco, discussed "Recent Advances in Clinical Endocrinology" before the San Diego County Medical Society May 9.

CONNECTICUT

Dr. Cowdry Lectures at Yale.—Edmund V. Cowdry, Ph.D., professor of cytology, Washington University School of Medicine, St. Louis, will deliver the Woodward lecture at the Sterling Hall of Medicine, May 24, under the auspices of the department of anatomy, Yale University School of Medicine, New Haven. His subject will be "Problems of Ageing."

Grant for Child Research.—The General Education Board of the Rockefeller Foundation has made a grant-in-aid of $85,000 to be distributed over a period of five years, and the Carnegie Corporation has appropriated the amount of $10,000 a year for three years in support of the clinic of child development at the Yale University School of Medicine, New Haven. Under the direction of Dr. Arnold L. Gesell, New Haven, the clinic is continuing its systematic studies of the behavior of infants. A new program which these grants make possible will give special attention to the medical aspects and clinical applications of research in child development, it was announced.

Society News.—Dr. Louis S. Goodman, New Haven, addressed the Hartford County Medical Association April 4 on "Recent Developments in the Therapeutics of Pain."——The Middlesex County Medical Society was addressed in Cromwell April 13 by Dr. Lewis W. Brown, Newark, N. J., on "Allergy in General Practice" and George M. Dutcher, Ph.D., Middletown, "Since Horse and Buggy Days."——At a meeting of the New London County Medical Association, New London, April 6 Dr. Samuel J. Kopetzky, New York, discussed socialized medicine.——Dr. James Raglan Miller, Hartford, addressed the Tolland County Medical Association April 18 in Somers on office gynecology.

ILLINOIS

Personal.—Dr. Walter C. Earl, Cuernavaca, Morelos, Mexico, has been appointed director of the Champaign-Urbana health district, it was recently reported.——Dr. Julius B. Stokes has resigned as superintendent of the Livingston County Sanatorium, Pontiac, effective April 1.

State Medical Election.—Dr. James S. Templeton, Pinckneyville, was chosen president-elect of the Illinois State Medical Society at its annual meeting in Rockford May 4. Dr. James H. Hutton, Chicago, was inducted into the presidency. Dr. Joseph S. Lundholm, Rockford, was elected first vice president, and Dr. Harold M. Camp, Monmouth, and Dr. A. J. Markley, Garden Prairie, were reelected secretary and treasurer respectively. The next annual meeting will be in Peoria.

Chicago

Dr. Taliaferro Made Distinguished Service Professor.—William H. Taliaferro, Ph.D., dean of the division of biological sciences and professor of parasitology, University of Chicago, was awarded the Eliakim H. Moore Distinguished Service Professorship May 4. Dr. Taliaferro received the award in recognition for his work in tropical diseases. The Moore professorship was established in 1927 in recognition of Dr. Moore, professor of mathematics at the university from 1896 to 1931.

Society News.—The Chicago Pathological Society was addressed at its annual meeting May 8, among others, by Drs. Edwin F. Hirsch and Russell H. Morgan on "The Causal Significance to Traumatic Ossification of the Fibrocartilage in Tendon Insertions."——At a meeting of the Chicago Ophthalmological Society May 8, the speakers were Drs. Harry S. Gradle and Daniel Snydacker on "Report of Three Cases of Retinal Detachment Occurring in Glaucoma"; Arthur Weil and Leo L. Mayer, "Attempts to Produce Experimental Tumors of the Eyeball," and Stephan van Wien, "The Leland Refractor: A Method for Refraction Under Binocular Conditions."——Dr. Albert Graeme Mitchell, Cincinnati, will speak on "What I Don't Know About Endocrines" before the Chicago Pediatric Society May 23.

IOWA

Annual Renewal Fees Due Before June 1.—All licenses to practice medicine and surgery in Iowa expire annually on June 30. To renew such a license a licentiate must make a written application to the state department of health before June 1, enclosing the renewal fee of $1. If a license expires by reason of the licentiate's failure to renew it, it can be reinstated without reexamination only on the recommendation of the state department of health and the payment of the overdue fees.

KANSAS

Library for Sedgwick County.—At a meeting of the Sedgwick County Medical Society, Wichita, February 7, the members voted unanimously to establish a medical library. New quarters taken by the society will provide space for the library reading room, the executive secretary's office, the medical service bureau office and a large reception room allowing space for library shelves. A librarian will be employed to catalogue and index material and assist in reference work, according to the *Medical Bulletin*.

MICHIGAN

University News.—A grant of $2,000 from Parke Davis & Co. will provide for a year's research at the Wayne University College of Medicine into the cause and treatment of peptic ulcer. Dr. David Sandweiss, instructor in clinical medicine, and M. H. F. Friedman, Ph.D., research associate in physiology, with rank of instructor, will be in direct charge of the work, while Thomas L. Patterson, Ph.D., will supervise the research. General investigations of peptic ulcer conducted during the past two years by the department of surgery will be continued in collaboration with the new work.

Personal.—Dr. Alexander W. Blain, Detroit, formerly president of the Wayne County Medical Society, has been appointed to the state commission of conservation.——Governor Dickinson has appointed Dr. Henry Allen Moyer, Charlotte, his personal physician, to the state service in the capacity of medical secretary, it was reported.——Dr. Charles R. Smith, formerly on the staff of the William H. Maybury Sanatorium, Northville, has been appointed medical superintendent of the Cooper Country Sanatorium, Houghton, succeeding Dr. George

McL. Waldie, resigned.——The library of the late Dr. Stephen H. Knight, Detroit, has been donated to the Wayne County Medical Society by his son Rufus.

Outbreak of Smallpox.—Newspapers reported April 12 that sixteen basketball teams were involved in an outbreak of smallpox while playing in a tournament in Mount Pleasant recently. The sixteen competing teams represented schools at Flushing, Alma, Sandusky, Evart, Perrinton, Gladwin, Lake City, West Branch, Carson City, Mecosta, Alabaster, Roscommon, Weidman, Crystal, Fowler and Mount Pleasant. In addition to the areas threatened by outbreaks directly related to the Mount Pleasant tournament, many other counties have been reporting smallpox cases, it was reported. Up to April 12, 192 cases had been reported throughout the state, constituting one of the greatest smallpox threats in recent years. For one month prior to this report seventeen counties reported seventy-one cases; these counties included Roscommon, Gratiot, Mecosta, Montcalm, Osceola, Muskegon, Allegan, Isabella, Cass, Genesee, Gladwin, Hillsdale, Midland, Missaukee, Ottawa, Presque Isle and Shiawassee. The state department of health secured six graduate physicians from the University of Michigan School of Hygiene and Public Health to assist local authorities in those counties having no full time health departments, it was stated.

MINNESOTA

Personal.—Dr. Gerald Taylor Evans, assistant professor of physiological chemistry, Yale University, New Haven, Conn., has been appointed associate professor of medicine and director of chemical and metabolic laboratories at the University Hospital, University of Minnesota. Dr. Evans graduated at McGill University Faculty of Medicine, Montreal, in 1932; he received his degree of doctor of philosophy from the University of Pennsylvania in 1937.

Society News.—Dr. Jesse G. M. Bullowa, New York, delivered the annual address before the Minnesota Pathological Society April 18 on "Specific Treatment of the Pneumococcic Pneumonias." The society was recently addressed by Drs. James S. McCartney, Minneapolis, on "Relation of Age and Site of Operation to Postoperative Pulmonary Embolism" and Fred G. Kolouch, Schuyler, Neb., "Role of the Lymphocytes in Acute Inflammation."——Recent meetings of the Scott-Carver County Medical Society were addressed in Shakopee and Minneapolis respectively by Drs. Edgar W. Bedford, Minneapolis, on "Clinical Aspects of Gallbladder Disease"; Ames W. Naslund, St. Paul, on "X-Ray Diagnosis in Gallbladder Disease"; Carl O. Rice, Minneapolis, "Indications for Surgery of the Thyroid Gland" and Chauncey N. Borman, Minneapolis, "X-Ray Measurements of the Female Pelvis."——Dr. Kenneth A. Phelps, Minneapolis, presented a paper before the Minnesota Academy of Medicine, St. Paul, April 12 entitled "Early Cancer of the Larynx."

MISSOURI

Society News.—Dr. Harold E. Petersen, St. Joseph, discussed pyelitis before the Buchanan County Medical Society recently.——The St. Louis Medical Society held a round table discussion on arthritis April 21 with Dr. Ralph A. Kinsella as the leader; one on delayed operation in acute peritonitis following ruptured appendicitis was held May 5 with Dr. Robert Elman as the leader.

Medal to Dr. Jacobsen.—Carlyle F. Jacobsen, Ph.D., professor of medical psychology, Washington University School of Medicine, St. Louis, was presented with the Howard Crosby Warren Medal at the annual dinner of the Society of Experimental Psychologists in Princeton, N. J., April 2. According to the New York *Times*, the medal was awarded for Dr. Jacobsen's "Description of the Functions of the Frontal Lobes of the Brain."

Personal.—Dr. William F. McCarthy has been appointed health officer of Jackson County, according to the *Weekly Bulletin* of the Jackson County Medical Society. Dr. McCarthy is attending the Graduate School of Public Health Administration of the University of Michigan, Ann Arbor.——Dr. Felix Deutsch, a member of the faculty of the University of Vienna from 1919 to 1935, has been made associate professor of psychosomatic medicine at the Washington University School of Medicine, St. Louis.

Health Department to Reorganize.—Full authority was given to Dr. Edwin H. Schorer, director of the Kansas City Health Department, April 27, "to clean out politics from the city health department," according to the Kansas City *Star*. Mayor Smith at the same time recognized the leadership of the Jackson County Medical Society in any move to revamp the health department. He asked Dr. Schorer to assemble a committee of doctors from the society at once to work with the health director "in reorganizing the health department 'along efficient lines and with no political strings attached—none whatsoever.'"

NEW JERSEY

New Officers of State Medical Board.—New appointments to the New Jersey State Board of Medical Examiners include those of Dr. Samuel Barbash, Atlantic City, A. Stanley Myers, D.C., Jersey City, and Dr. John H. Rowland, New Brunswick, succeeding Dr. Henry B. Diverty, Woodbury, Walter Seth Kipnis, Ph.D., West New York, and the late Dr. William E. Darnall, Atlantic City.

NEW YORK

State Medical Election.—Dr. James H. Borrell, Buffalo, was chosen president-elect of the Medical Society of the State of New York at its annual meeting in Syracuse April 25, and Dr. Terry M. Townsend, New York, was installed as president. Other officers include Drs. Aaron Sobel, Poughkeepsie, second vice president, and Peter Irving, New York, secretary. The 1940 annual session will be held in Buffalo.

Hospital Named in Honor of Physician.—Dedication ceremonies were held April 20 to mark the renaming of the Buffalo City Hospital as the Edward J. Meyer Memorial Hospital. The late Dr. Meyer was for many years president of the hospital board. Kenneth Goodner, Ph.D., of the Rockefeller Institute for Medical Research, New York, was the guest speaker, discussing newer aspects of pneumonia. Other speakers included Drs. Carlton E. Wertz, who reviewed the life of Dr. Meyer; Dr. Abraham H. Aaron on the relationship between the hospital and the University of Buffalo; Chancellor Samuel P. Capen of the university, Dr. Herbert H. Bauckus and Commissioner Thomas W. H. Jeacock of the county department of social welfare. The ceremonies were under the auspices of the Medical Society of the County of Erie, the Buffalo Academy of Medicine and the consulting, visiting and resident staffs of the hospital.

New York City

Eighth Harvey Lecture.—Dr. Albert Szent-Gyorgyi, professor of medical chemistry, University of Szeged, Hungary, delivered the eighth Harvey Lecture of the current series at the New York Academy of Medicine May 18. His subject was "Biological Oxidation and Vitamins."

Goat's Milk.—About 150 milch goats are supplying the demand for goat's milk in the city, according to New York *Medical Week*. The three dairies furnishing the milk operate under a permit from the city department of health. Although goat's milk is popular in Europe, only approximately 250 quarts of it are consumed in the city every day, it was stated. Each of the three goat dairies produces certified milk, and one of them also produced pasteurized milk.

Retiring Members of Rockefeller Staff.—Five members of the Rockefeller Institute for Medical Research are retiring from active work, having reached or passed the age of 65 years. They are Drs. Alexis Carrel, who announced his retirement last year, Florence R. Sabin, who retired early this year; Karl Landsteiner, Phoebus A. Levene and Winthrop J. V. Osterhout, Ph.D. According to *Science*, the mandatory retirement rule is being enforced in all organizations with which the Rockefeller foundations are connected. It is stated that pensions will be given and that every laboratory facility will be provided to enable those who retire to continue their research work on their own responsibility if they care to do so.

Exhibit Presented to Army Museum.—The anatomical collection assembled by the late Dr. George Sumner Huntington, for many years professor of anatomy at Columbia University College of Physicians and Surgeons, has been presented by the medical school to the Army Medical Museum, Washington, D. C. This is said to be the largest collection in the United States and was formerly used in teaching. When the medical school was in its old location at Fifty-Ninth Street, the collection was viewed by many visitors, but in recent years lack of space at the new Medical Center has made an exhibit impossible, it was said. For this reason it was decided to transfer it to the Army museum, where it will be available for students from all parts of the world.

Society News.—At a joint meeting of the Medical Society of the County of Kings and Academy of Medicine of Brooklyn, April 18, Murray J. Shear, Ph.D., and Dr. Stanley P. Reimann, Philadelphia, discussed "Experimental Aspects of Carcinogenic Substances" and tumor grading, respectively.—— The Brooklyn Thoracic Society was addressed April 21 by Drs. Edgar Mayer on diagnosis of early pulmonary tuberculosis and Paul Geary, "The Operation of Extrapleural Pneumothorax."—— A symposium on the treatment of peripheral vascular disease was presented at a meeting of the New York Academy of Medicine May 4 by Drs. Irving Sherwood Wright, Edgar V. Allen, Rochester, Minn., and Reginald H. Smithwick, Boston. Drs. James C. White, Boston, and Beverly Chew Smith discussed the papers.—— Dr. Smiley Blanton, among others, addressed the New York Neurological Society at a joint meeting with the section of neurology and psychiatry May 2 on "Psychiatric Study of Some Miraculous Cures at Lourdes."

NORTH CAROLINA

Plaque in Honor of Dr. McBrayer.—A plaque was unveiled April 19 in the auditorium of the state tuberculosis sanatorium, Sanatorium, in honor of the late Dr. Louis B. McBrayer. Dr. Paul H. Ringer, Asheville, was the principal speaker. Dr. McBrayer served for twenty-one years as secretary of the Medical Society of the State of North Carolina and at one time as president; he was president of the Southern Conference on Tuberculosis 1925-1926, managing director of the North Carolina Tuberculosis Association, 1915-1937, and superintendent of the state tuberculosis sanatorium at Sanatorium, 1914-1924.

OHIO

Dr. Krogh Gives Hanna Lecture.—Dr. August Krogh, professor and director of the Zoophysiological Laboratory, University of Copenhagen, Denmark, delivered the forty-fourth Hanna Lecture at the Institute of Pathology, Cleveland, May 5. His subject was "The Regulation of the Circulation as Observed in Changes of Posture in Man."

Director of Social Hygiene Society Appointed.—Dr. Richard W. Weiser, medical director of public schools in Kenmore, N. Y., has been appointed executive secretary of the Cincinnati Social Hygiene Society to succeed Dr. Carl A. Wilzbach, who recently became city health commissioner. Dr. Weiser received his medical degree at the University of Pennsylvania School of Medicine, Philadelphia, in 1927. He has been with the Kenmore school system for six years.

Society News.—Dr. Charles E. Kiely, Cincinnati, among others, addressed the Adams County Medical Society April 19 in West Union on "Dementia Praecox and Its Treatment."——Drs. Frederick G. Maurer and Melvin A. Mulvania, Lima, addressed the Henry County Medical Society April 11 in Napoleon on "Clinical Aspects of the Common Cardiac Arrhythmias" and "Hemorrhage in Pregnancy" respectively.——Dr. John A. Malcolm, Pittsburgh, addressed the Columbiana County Medical Society in Lisbon April 11 on "Neurasthenia and Recent Advances in Neurology."

PENNSYLVANIA

Society News.—Drs. Russell L. Haden and James A. Dickson, Cleveland, discussed medical and surgical aspects, respectively, of arthritis at a meeting of the Westmoreland County Medical Society April 27 at the Mountain View Hotel near Greensburg.——Dr. John A. Kolmer, Philadelphia, addressed the Blair County Medical Society, Altoona, April 25, on "Immunology of Anterior Poliomyelitis."—— Dr. Joseph A. Hepp, Pittsburgh, addressed the Fayette County Medical Society in Uniontown May 4 on "Endocrine Treatment of Menstrual Disorders."

Philadelphia

Portrait Presented.—The senior class of Jefferson Medical College presented a portrait of Dr. Frank Crozer Knowles, professor of dermatology, to the college April 28. The portrait was painted by Frederick Gill, Philadelphia artist. Dr. Knowles, who graduated from the University of Pennsylvania in 1902, has been professor of dermatology at Jefferson since 1919.

Course in Internal Medicine.—The Pennsylvania Hospital announces a general course in internal medicine for graduate physicians to be given June 5-23. Lecturers will be Drs. William D. Stroud, on cardiology; Lawrence S. Carey, gastroenterology; David L. Farley, hematology; Burgess L. Gordon, diseases of the lung; Norman P. Shumway, diseases of the kidney; Garfield G. Duncan, metabolism; John T. Bauer will conduct pathologic conferences and Paul A. Bishop, roentgen ray conferences. The fee is $100.

WEST VIRGINIA

Interstate Meeting.—The Greenbrier Interstate Medical and Surgical Society held its first meeting at the Greenbrier Hotel, White Sulphur Springs, April 17. The speakers were Drs. Marvin Pierce Rucker, Richmond, on "Further Experience with Knotless Sutures in Immediate Perineorrhaphy"; John M. T. Finney Jr., Baltimore, "Developments in the Study and Care of Patients Suffering with Appendicitis," and Louis George Herrmann, "Practical Aspects of Circulatory Disturbances in Extremities." This meeting was the first of neighboring medical societies in Virginia and West Virginia.

WYOMING

Lectures on Pediatrics.—A series of postgraduate lectures on pediatrics will be presented throughout Wyoming May 22-June 9 by Dr. Clifford D. Sweet, chief of staff at the Children's Hospital of the East Bay, Oakland. The series is part of a plan for postgraduate work for Wyoming physicians in obstetrics and pediatrics, approved at the annual meeting of the Wyoming State Medical Society in August 1938.

GENERAL

Prize Awarded for Pellagra Cure.—Conrad Arnold Elvehjem, Ph.D., since 1936 professor of agricultural chemistry, University of Wisconsin, Madison, was awarded a prize of $1,000 at the closing meeting of the American Institute of Nutrition in Toronto April 26 for his discovery that nicotinic acid would cure pellagra. Dr. Elvehjem was born in McFarland, Wis., in 1901.

Meeting of Surgeons.—The third annual assembly of the International College of Surgeons will be held at the Hotel Roosevelt, New York, May 21-25. The program includes many speakers from the United States and other countries. At the banquet, Tuesday evening, the speakers will include Gen. Dr. F. C. Najera, ambassador from Mexico to the United States, Major Vouvier, and Dr. Max Thorek, Chicago.

Rheumatism and Arthritis.—An editorial committee of the American Rheumatism Association, headed by Dr. Philip S. Hench, Mayo Clinic, Rochester, Minn., has published the fifth rheumatism review of American and English literature on "rheumatism." This review assembles in one place most of the references on the subject and contains numerous editorial and critical comments by its compilers. The review appeared in the January and February issues of the *Annals of Internal Medicine* and is also available in reprint form from the secretary of the American Rheumatism Association, Dr. Loring T. Swaim, Boston.

Society News.—The eleventh annual meeting of the Aero Medical Association will be held at the Hollywood Beach Hotel, Miami, November 3-5.—— The twenty-second annual meeting of the American Dietetic Association will be held at the Hotel Ambassador in Los Angeles August 27-31; the speakers will include Agnes Faye Morgan, Ph.D., University of California, on "The Dietitian's Place in the Hospital Research Program"; E. Neige Todhunter, Ph.D., State College of Washington, "The Newer Knowledge of Vitamin C in Health and Diseases," and Dr. Albert H. Rowe, Oakland, "Allergy."——The American Society of X-Ray Technicians will hold its fourteenth annual meeting at the McAlpin Hotel, New York, June 27-30.

Special Society Elections.—Mr. John O. Steel, Pine Bluff, Ark., was installed as president of the Mid-West Hospital Association at its annual meeting in Hot Springs National Park. Dr. Herbert A. Black, Pueblo, Colo., was chosen president-elect. The association includes the states of Arkansas, Colorado, Kansas, Missouri and Oklahoma.——Frank B. Jewett, Ph.D., president, Bell Telephone Laboratories, New York, was elected president of the National Academy of Sciences at its annual meeting in Washington April 26, succeeding Frank R. Lillie, Ph.D., Chicago. Frederick E. Wright, Ph.D., of the geophysical laboratory of the Carnegie Institu-

tion, Washington, was reelected home secretary.——Dr. Fred Kuhlman, St. Paul, Minn., was elected president of the American Association on Mental Deficiency at its annual meeting at the Palmer House May 6. Other officers include Meta A. Post, Ph.D., Newark, N. J., vice president, and Dr. E. Arthur Whitney, Elwyn, Pa., secretary-treasurer. The 1940 meeting will be held in May in Atlantic City.

Research on Problems of Alcohol.—The recently organized Research Council on Problems of Alcohol has issued a report outlining its program of research as it has been developed at present. It will be the policy of the council to conduct research, to arrive at conclusions based on research, to present the facts in suitable form to interested groups and to encourage intelligent discussion of the facts, according to the statement. It will not arrive at conclusions based on unscientific assumptions, engage in propaganda, lobby for liquor control laws or participate in political campaigns. The following problems have been selected for study and some of them assigned as indicated:

A critical survey of the conclusions to date of all significant studies regarding the effects of alcohol on the individual

Polyneuritis and Korsakoff's psychosis in the alcohol addict, to be conducted by Bellevue Hospital, New York

Toxic factors in alcoholism, to be conducted by the New York Psychiatric Institute

A critical survey of all studies completed and under way which deal with the relation of alcohol to traffic accidents.

The role of alcohol in liver cirrhosis, to be conducted by Bellevue Hospital

Psychological factors in deterioration and recovery in cases of acute alcoholism and alcoholic psychosis

Research will be conducted in three fields: the effects of alcohol on the individual, the effects of alcohol on society and the effectiveness of industrial and legal control. Accompanying the research program will be a program of education in four fields; schools and colleges, community leaders and the adult population, manufacturers and distributors of alcoholic beverages, law enactment and law enforcement agencies. Harry H. Moore, Ph D, is director of the council, which has headquarters in the R C. A. Building, New York.

Osteopathy Vetoed in New York.—On May 10, Governor Herbert H. Lehman of New York vetoed a bill which would have permitted licensed osteopaths to use instruments for minor surgical work, as well as use anesthetics, antiseptics, narcotics and biologic products. In a message explaining his action, the governor wrote:

To the Assembly

There has been great misunderstanding with regard to this bill Many people apparently believe that the practice of osteopathy as now carried on depends on my approval of the bill This, of course, is completely contrary to the facts

Any persons now licensed or hereafter licensed as doctors of osteopathy are, regardless of my action on the bill, permitted to render exactly the same services as in the past Their authority to carry on the functions now performed is in no way curtailed or abridged

VALUE OF OSTEOPATHY CONCEDED

There is no question as to the substantial value and usefulness of osteopathy. This is generally conceded and recognized This bill would, however, give all licensed osteopaths broad additional powers. It would permit all licensed osteopaths to use instruments for minor surgical procedures, to administer anesthetics and antiseptics, and to prescribe narcotics and biological products

The additional authority now asked by the osteopaths may be far-reaching in its effect A minor operation, if not properly performed, I am advised, may be more serious in its effect upon the patient than some of the so called important operations

The administering of drugs and biologicals where there is not sufficient training and experience with regard to their effect on the patients may lead to serious ill effects

Undoubtedly many of the persons now licensed to practice osteopathy in this State have had broad training and experience in matters relating to medicine and surgery. On the other hand, many of the osteopaths practicing in this State were licensed prior to the setting of the present high standards of training and have had little or no later experience in medicine or surgery.

LICENSING METHODS RECALLED

In addition, a very substantial number of the osteopaths now practicing in this State receive their licenses not through examinations within the State but by endorsement of licenses granted to them in other States Some of them are graduates of osteopathic schools which are no longer recognized by our board.

In my opinion legislation should provide that applicants for licenses and those who already hold licenses as osteopaths but who now desire additional powers should be required to satisfy the Board of Regents either by submitted credentials or by examination that they have had the proper instruction and training in surgical procedure and drug therapy to justify the granting of the additional powers set forth in this bill

In this way the Regents would be able to determine those who are actually qualified to use instruments for minor surgical procedures, to administer anesthetics and antiseptics and to prescribe narcotics and biological products. The difficulty of providing for such determination by the Board of Regents does not seem to me great

The bill is disapproved

HERBERT H. LEHMAN.

CANADA

Society News.—Dr. Ralph M. Waters, Madison, Wis., addressed the Academy of Medicine of Toronto April 4 on "The Development of Anesthesiology." Dr. Joseph Brennemann, Chicago, addressed the academy recently on "Acute Abdominal Conditions in Childhood." Dr. Eric Miles Atkinson, New York, addressed a combined meeting of the sections on otolaryngology and neurology and psychiatry recently on "Localized Nonsuppurative Encephalitis Resulting from an Adjacent Focus of Infection—Some Pathological and Clinical Considerations."——Dr. John H. MacDermot, Vancouver, delivered the annual Osler Lecture of the Vancouver Medical Association March 7 on "The Layman and the Doctors."

Summer School Clinics.—The Vancouver Medical Association will hold its annual summer school clinics June 6-9; participants will include:

Dr. Leighton C. Conn, professor of obstetrics and gynecology, University of Alberta Faculty of Medicine, Edmonton.

Dr. Emile F. Holman, professor of surgery, Stanford University School of Medicine, San Francisco.

Dr. Charles P. L. Mathe, San Francisco.

Dr. Frank R. Menne, professor of pathology, University of Oregon Medical School, Portland.

Dr. Dwight L. Wilbur, associate clinical professor of medicine, Stanford University School of Medicine, San Francisco.

Further information may be obtained from Dr. William W. Simpson, secretary, 203 Medical-Dental Building, Vancouver, B. C.

Medical Research Facilities in Canada.—The National Research Council of Canada recently made a survey of medical research facilities in the Dominion. A conclusion was reached that immediate attention should be given to tuberculosis and rheumatic diseases. Projects are to be initiated in a number of institutions. In the field of cancer research the committee decided to aid the work on standardization of dosage which has been undertaken in cooperation with the National Physical Laboratory in England and the National Bureau of Standards in Washington, D. C., making use of high voltage equipment in the National Research Laboratories at Ottawa. The committee also proposed to aid in developing research in various institutions throughout Canada, and these institutions have been invited to undertake work under the auspices of the committee of which Sir Frederick Banting, Toronto, is chairman.

FOREIGN

Congress on Medical Hydrology.—The sixteenth International Congress on Medical Hydrology, Climatology and Geology will be held at the Strasbourg Faculty of Medicine October 8-11. Information may be obtained from M. le Prof. Vaucher, Institut d'Hydrologie et de Climatologie, 1 place de l'Hôpital, Strasbourg.

Societies Merge to Form Faculty of Radiologists.—The British Association of Radiologists and the Society of Radiotherapists of Great Britain have joined to form the Faculty of Radiologists, according to *Radiology*. The work of the new organization will be carried on at the old office of the British Association of Radiologists, 32 Welbeck Street, London, W.1.

Society News.—The National Association for the Prevention of Tuberculosis of Great Britain will be held in Belfast, Ireland, June 29 to July 1. The subjects for discussion will be "Problems of Organization and Local Administration of Tuberculosis Schemes"; "Tuberculosis in the Adolescent" and "Architectural Problems in Connection with Tuberculosis Institutions."——The German Roentgen Society will hold its annual meeting in Stuttgart May 24-27.

Congress on Industrial Medicine.—The second "Journées Internationales de Pathologie et d'Organisation du Travail" is to be held in Paris under the patronage of government officials and with the cooperation of various medical and industrial organizations. The program lists the following subjects of reports to be presented: "Hygienic Conditions in Soldering Works"; "Etiology and Pathogenesis of Occupational Dermatitis"; "Various Systems of Compensation for Occupational Disease" and "Toxicologic Study of the Principal Constituents of Special Kinds of Steel." There will be many visits to industrial plants and to hospitals. The languages of the congress will be German, English, Spanish, French and Italian. All correspondence should be addressed to the president of the congress at the Institut Medico-Legal, Place Mazas, Paris XII. Dr. Guy Hausser is the secretary in charge of organizing the congress.

Thomas's Splint in War Surgery

In lectures on the treatment of war wounds, delivered at the British Postgraduate Medical School, Col. J. M. Weddell of the Army Medical Corps stated that the army relied on the large-ringed Thomas splint in the evacuation of the majority of fracture patients from the front line to the casualty clearing station. The splint is applied over the boot and clothing, and the ring is packed anteriorly and laterally with tow or wool to retain it against the tuber ischii. The fracture is supported with Gooch splinting or Cramer's wire. Extension is obtained by means of a skewer through the waist of the boot or a clove-hitch, around the ankle, tied to the distal end of the splint. The splint is suspended to a bar fitting over the stretcher. Many modifications of Thomas's splint have been suggested, such as collapsible splints and half-ringed splints. Colonel Weddell had the opportunity of discussing a number of points with a committee composed of four members of the council of the Royal College of Surgeons. It was agreed that for the evacuation of casualties the original Thomas model was the most satisfactory. As one member said, "A Thomas splint altered is a Thomas splint spoiled."

It was agreed that internal traction by pins and wires was unsafe unless first class asepsis could be assured. Thus skeletal traction in dressing stations was ruled out and probably also in casualty clearing stations from which patients are evacuated by train. Plaster of paris in the form of supporting slabs would be of great use in casualty clearing stations, but encircling compound fractures with circular plaster bandages was dangerous in the early stages. Extensive use should be made of blood transfusions, and blood stored in refrigerators should be used in dressing stations. Drip transfusion would be of great use in casualty clearing stations. Advanced operating units were not advised, as it would be better to get the patients to the casualty clearing stations, where they could be operated on and nursed under better conditions. Patients would not stand evacuation well after serious operations. Gas and oxygen was the best anesthetic for serious operations, but it involved the use of heavy, cumbersome cylinders, to supply which might be difficult. For many operations ether should be the standard anesthetic. Barbiturates and spinal anesthesia were dangerous for patients already in a condition of shock.

In the great war the introduction by Sir Robert Jones of the use of Thomas's splint for the transport of patients with gunshot fractures of the femur greatly reduced the mortality from these fractures. The observation made that Thomas's splints are so perfect that attempts to improve them have only the opposite effect is not new. The passage of time has only increased Thomas's reputation, while it almost uniformly dims the reputation of men famous in their day. During his life Thomas received little recognition. When the American orthopedist John Ridlon visited the English clinics he found that the surgeons did not have a good word for Thomas, but of him he wrote the great epitaph "He did more good new things for orthopedics than all the rest since Hippocrates."

Prolapsed Intervertebral Disk

At the Royal Society of Medicine Dr. J. Grafton Love of the Mayo Clinic opened a discussion of prolapsed intervertebral disk. The typical finding at operation was edema of the posterior nerve root in the affected segment. The prolapse was relatively uncommon, though Dr. Love was able to give statistics of 300 cases. It was three times commoner in men than in women and the average age at the time of operation was 40 years, but this was no true indication of the age of onset of symptoms, of which there was a long history in many cases. The greatest incidence was in the lumbar region, the fourth and fifth disks being those liable to be affected, thus accounting for the dominant symptom, sciatica. Thirty-seven per cent of the patients gave a history of injury immediately preceding the onset of symptoms. Nocturnal pain was an important symptom, as were exacerbations on coughing and sneezing. The achilles jerk was absent. Examination showed spasm of the erector spinae and obliteration of the lumbar curve. The total protein in the cerebrospinal fluid was increased, and in two thirds of the cases radiographic examination with iodized oil revealed narrowing of the canal. The treatment was laminectomy with removal of the protruding cartilage, which gave gratifying results.

The neurologist Dr. C. P. Symonds had experience of twenty-two cases, in which the pressure was on the cord in fifteen and on the cauda equina in seven. He discussed the differential diagnosis from other conditions, such as tumors. Important features were the relation of the pain to injury and its exacerbation by coughing and spinal movements. Remission of symptoms was noteworthy. Patients in whom the lumbar part of the spine was affected showed pain in the lower part of the back, related to effort and posture. Elsberg had stated that the posterior columns were spared in the sensory loss that might ensue, but Symonds had found that this did not hold in seven of his cases. Spinal tumors were distinguished by the fact that on the whole the sequence of events suggested anterior compression, while prolapsed disk caused posterior compression. Disseminated sclerosis, with its well known remission of symptoms, might give rise to difficulty of differential diagnosis. The question of sciatica presented difficulty, for his experience of sciatica was that patients eventually recovered, whatever the treatment. How many sciatic patients with prolapsed disk recovered with rest alone before the days of diagnosis of the cause?

Mr. Julian Taylor said that three types of pain were caused by prolapsed disk: (1) pain in the vertebrae, (2) pain referred from the vertebrae and (3) pain referred from the nerve pinched. The last was the most persistent. From his operative experience he rejected the theory of hernia of the nucleus pulposus. The substance removed was white necrotic material. One of his patients, a heavy man, hurt his back in a turn with professional acrobats. They threw him in the air and caught him at their feet. Extreme kyphosis developed.

Evacuation of the London School Children

If the latest development of "civilized warfare," the bombing of crowded cities, should occur in this country, it has been arranged to spare children as far as possible. Plans complete to the last detail for the stupendous task of evacuating the school children of London have been issued to the heads of the schools in a circular of 5,000 words. As many as 1,300,000 children and the persons accompanying them will need to be moved out in organized parties in a short time. The children will be accompanied by their teachers and when under 5 years by their mothers or other responsible persons. Blind persons and expectant mothers will be removed at the same time. The government has made a survey of the accommodations available in the reception areas, which shows that there will be no scarcity of homes where the householders are willing to look after the children. In an emergency two messages will be sent to the schools. When the first, "Get ready for evacuation," is received head teachers will notify all assistant teachers and helpers. The second message will give the date of evacuation, and each school will then form a unit or school party. The children will march to the train in squads of fifty. Divisional officers have been appointed for the quick settlement of local problems. They will be responsible for the local planning of routes to the

entraining stations and arranging the order in which schools will be entrained. The children will carry a change of clothing, night attire, toilet requisites, sufficient food for the day and their gas masks. It will not be possible to take at the same time children who are sick at home or who are so crippled that they cannot walk.

PARIS

(From a Special Correspondent)

April 15, 1939.

Alcoholism

It is estimated that the annual expenditure by the French on their apéritifs and small drinks is 6 billion francs. A committee of the Académie de médecine has been charged to formulate recommendations and to submit to the public authorities the resolutions that sociologists, biologists and physicians regard as indispensable. Strict enforcement of existing laws is demanded, especially those which concern the number of drinking shops and the hours during which alcohol may be sold. Moreover, an important reduction of their number and their closing under certain circumstances such as strikes and elections are asked. These representations allow one to understand the role that politics plays in the spread of alcoholism.

The Société médicale des hôpitaux of Lyons insists on the prohibition of drinks of high alcoholic content and the sale of alcohol in glasses. It believes that tax reductions should be allowed drink shops that do not sell alcohol, that habitual drunkards should be denied permits to manage such places and the benefit of insurance protection and that drunkenness should no longer be regarded as an attenuating circumstance by courts; in short, that an intensive campaign should be undertaken against this social danger.

The French Population

France had 36,000,000 inhabitants in 1850. She has 42,000,000 today, but one must deduct 2,500,000 aliens. In 1850 there were only 400,000 aliens. Italy, England and Germany have doubled their population while France has grown by only one tenth. In 1851 three Frenchmen lived in the country to one in the city. Today more people live in the city than in the country and one eighth of the French population lives in Paris and its outskirts.

This exodus from country to town coincided with the lowering of the birth rate. Although the number of marriages remains stationary, that of children per marriage is rapidly falling. The difficulty is that French women either no longer can or no longer want to bear children. German family life faced the same situation for twenty-five years, until Hitler ordered economic measures, which have fully succeeded. At present German families in which the mother's age ranges from 20 to 24 years have twice as many living children as French families in similar situations.

The remedies proposed by Moine, who presented extensive evidence of this situation before the Académie de médecine, aim at establishing an economic and financial equilibrium between large families, homes without children and single men and women, since half of the French homes entrust to the others the care of maintaining the population level. It is not a question of penalties but solely of establishing a reasonable balance between those who rear children and those who do not.

Vitamins in the Prevention of Pellagra

The pathogenesis of aphthae is unknown. Professor Cachera at a reunion of the Société médicale des hôpitaux of Paris reported satisfactory results from the administration of nicotinic amines and nicotinic acid in the treatment of this disease. Cure took place in a few days in several cases in which the condition had been refractory to other treatments. The speaker wondered whether aphthae is an atypical form of pellagra. It is possible that the satisfactory results induced by administering liver extract in the treatment of aphthae may be due to the nicotinic acid amines present in the extract. Boule reported satisfactory results from the administration of nicotinic acid in a case of coproporphyrinuria. The patient was suffering from cirrhosis without ascites, hepatic insufficiency, local melanoderma, cerebral symptoms and colic spasm. Nicotinic acid induces rapid improvement of the general condition of the patient and rapid disappearance of porphyrinuria. This case suggests a possible connection between aphthae and pellagra in their relation to avitaminosis.

Electrofluoroscopy

Lian and Minot presented at the Société médicale des hôpitaux of Paris a fluoroscopic electrocardiograph which solves the difficulty of taking a film through the photographic tray and waiting for the negative before seeing how the heart functions. This apparatus makes it possible to see electrocardiograms and electrokymograms instantaneously. There remain some distortions to suppress, caused by the powerful amplifier used for transmission.

Lian and Minot used a cylindric screen, moved at uniform speed, in front of the oscillograph. Besides, the use of a mechanical oscillator, instead of a cathodic oscillograph, permits the use of an amplifier of small power. The recording consequently is continuous and regular and the period of phosphorescence long enough for observation. The apparatus consists of a large cylinder, its evolution measuring 1 meter, with the time marked on it. This cylinder turns in front of the luminous spot or spots and thus are made the electrocardiographic and kymographic tracings. The frequencies and amplitudes are faithfully reproduced. An interesting phase of the tracing may be preserved either by diverting the current toward the regular electrocardiogram or else by placing a piece of sensitized paper over the place of interest on the screen; the remaining light will be strong enough to leave an impression of the image on the emulsion.

The apparatus is simple and inexpensive. Its uses are manifold. It is possible to get an electrocardiogram for guidance in diagnosing at the bedside of the patient and to follow on the fluorescent screen the immediate effects of a medicament or to keep a patient during narcosis or childbirth under constant control. It may be most useful for psychologic experiments; the encephalographic tracing is drawn at will before the eye of the experimenter.

Anniversary of the Pasteur Institute

At the fiftieth anniversary of the founding of the Pasteur Institute most of the speakers preferred to arrange a program in which the students and former associates of Pasteur exhibited the results of their activity. Among these, Prof. M. L. Martin, present director of the institute, described Pasteur's methods and technics, in which he had been a direct collaborator. Prof. Gaston Ramon gave a summary of a fifty year old achievement of Pasteur, the fight against diphtheria. This was an occasion to defend anatoxin against recent attacks. Prof. Pasteur Vallery-Radot concluded the commemoration by reviewing the activity of Pasteur institutes in the struggle against social scourges, not only in French colonies but in many other countries.

Spanish Refugees

After Franco's victory, 200,000 Republican soldiers, of whom 12,000 were wounded, and 160,000 civilians took refuge in France, crossing the Pyrenees by eastern mountain passes. It was necessary to distribute this population quickly in different regions of France but, first of all, to isolate the infectious.

Delousing, cleaning and vaccination were done for this throng, which arrived like a rushing tide in complete disorder. A large number had been exposed to typhus.

Besides government and army physicians, many civilian physicians offered their services, as did the infirmaries of the Red Cross. Packets were requisitioned and transformed into floating hospitals. Three hundred of the 12,000 wounded died. The duty of according refuge was discharged in a satisfactory manner.

BERLIN

(From Our Regular Correspondent)

March 27, 1939.

News of the Universities

Of significance since the report on the universities in THE JOURNAL January 28, page 347, was the first conference of university presidents of Greater Germany, held early in March in Berlin at the invitation of the department of education for the reich. It is significant that the presidents of the German university at Prague, of the technical schools in Brünn and Danzig and of the Herder Institute at Riga participated. Minister of State Dr. Wacker, of the department of education, said that the time has arrived for the carrying out of all the reforms necessary to the organization of a common German university. Statewide unity has at last been attained in building up the German university system and German scholarship. Especially important are student enrolment in the universities, teaching personnel and plans for the German university system.

STUDENT ENROLMENT

The student enrolment for professions requiring an academic education is scarcely smaller than, for example, in 1911-1914 (68,000 students today compared with 72,000 at that time). However, the question assumes a different slant if the economic and military demands are taken into consideration. The decrease in the birth rate, the losses incurred in the World War and the elimination of Jews from the academic professions will become noticeable. There will be a shortage of about 30,000 engineers in 1942. Now there is need of 15,000 enrolments for callings that require an academic training. In the next few years an annual shortage of at least 8,000 graduates will have to be reckoned with. The number of college graduates eligible for university studies will fall from 36,000 in the current year to 32,000 in 1940 and probably to 27,000 in 1941. Specific data regarding the enrolment of medical students have not become known. Remedies must be sought. However, the quality of German students and of German scholarship may not be lowered.

TEACHING PERSONNEL

The law just passed regarding the salaries of university teachers establishes the economic security of those of the rank of instructor (dozent). This was a national necessity, for thereby scholarship, which is the greatest asset of German culture, can be furthered. It is hoped that in this way the danger of losing potential university material has been removed. The type of instructor who has no definite income in spite of reaching his fortieth year must disappear forever. Stipends and teaching assignments are not sufficient to insure a steady succession of teachers at the universities. To promote academic scholarship, university teachers must be relieved of financial worries.

PLANS FOR THE GERMAN UNIVERSITY

With the rise of new branches of learning the universities have largely lost the university concept and ideal of "universitas litterarum" that was valid in the last century. Born of specialized needs, specialized schools of higher learning have arisen. However, it is necessary to limit the number of training centers for specialized sciences and to concentrate them in a few universities. Furthermore, the assignment of functions among the individual universities is to be carried out according to a plan, the tradition of the individual university being taken into consideration. In Berlin a model university is being planned, in which the unity of German scholarship characteristic of the third reich is to be comprehensively represented. However, not even in Berlin are all the specialized sciences to be taught, but rather the fundamental subjects which compose the "universitas," namely, the humanities, jurisprudence and political science, medicine and the pure and applied sciences. These are the subjects that belong to the corporate whole of a university and to that of a technical school of higher learning.

UNIVERSITY SALARIES

The new law on the salaries of university teachers gives an insight into university life. It is the first governmental law of its kind. Until now the administration of the universities was subject to the individual German states. Although the incomes of teachers were fairly uniform, there were differences which frequently provided inducements when positions were to be filled. The basic salaries of full professors ranged between 6,900 and 14,000 marks, the average being about 11,000 marks. To this was added money for rent and various other items. Associate professors received a minimum salary of from 4,400 to 6,000 marks and a maximum of about 7,800 to 10,500 marks. Salaries in Prussia were somewhat higher. Special regulations governed the incomes in special cases for directors of institutes. Some states reserved the right to make exceptions in behalf of distinguished men whom they wanted to secure.

The new law creates a uniform basis for the entire country, inclusive of Austria and the Sudetenland. Full professors are to receive a basic salary of from 7,500 to 11,600 marks and, in special cases, as much as 13,600 marks; associate professors, from 5,700 to 9,000 marks, with a maximum of 11,600. Besides, both classes of teachers are to receive a share of the fees paid for their lectures. A definite income from course fees is guaranteed, the minimum being 1,000 and the maximum 7,000 marks. Provision has been made to grant further additions in special cases "to secure and retain excellent teaching ability." Presidents and deans receive special grants.

A new feature of the law is that now young instructors receive a definite salary of from 3,400 to 7,500 marks from the time of their appointment, together with compensation for rent. Previously "assistance" was granted only for two years and had to be accompanied by a statement of productive scholarship and also of financial circumstances. Besides, the leader of the instructors' club, whose position was political, had to give his opinion. "Assistance" could be withdrawn whenever this local officer regarded it fitting. The provisional phases of the salary system are now removed. Young instructors are thoroughly examined as to their political belief before they are admitted. The new law is a step toward the goal of a uniform law governing the university teachers of the country.

POLITICAL VERSUS ACADEMIC EDUCATION

Studentenführer Dr. Scheel said in February that nothing is more senseless than to assume that a political education is a hindrance to specialized academic training. Any one who thinks so neither has learned from history nor understands the nature of the present constructive program in Germany. The teacher who has no interest in politics is not wanted, for only by basing his specialized knowledge on the unity of Nazi philosophy can he attain his highest professional success. Great importance is attached to working together with the academic youth of other countries. For this reason efforts are made to enable every student to study abroad. The leadership of the universities must constitute a bridge to carry German ideas to other nations.

FOREIGN STUDY

Last year the question of studying abroad led to diplomatic inquiries. The foreign bureau of the student leadership requested students to consider Swiss universities for the summer semester of 1939, advising that two semesters spent in Switzerland would receive full credit. Aid was available to needy students and to those especially willing to volunteer. The condition attached to the offer required these students to take part first in Germany in the "labor association Switzerland," a special form of a Nazi training course for students who go abroad. The words "especially willing to volunteer" led to diplomatic steps by the Swiss government, with a request for elucidation, and an explanation was given.

GERMAN CLINICS IN PRAGUE

What happened in the German clinics in Prague was reported in THE JOURNAL January 7, page 72. For a time the plan was to remove the German schools of higher learning in Prague to the Sudetenland. This plan was not carried out. The winter semester was opened at the German university in Prague January 11, after a delay of two months caused by political events, under the leadership of the Nazi student body. Almost all Jewish students have been removed. The number of students at the German university (there is also a Czech university in Prague) is 3,000 instead of the former 5,000. The decrease is due in part to the elimination of Jews and in part to labor conscription and military service, which young Sudeten Germans must now undergo as members of the German reich. In the summer semester the complete reorganization of these two schools of higher learning after the pattern of the German universities is to become effective.

PALESTINE

(From Our Regular Correspondent)

Tel-Aviv, April 21, 1939.

Medical Refugees in Palestine

The rise of Hitlerism produced profound repercussions on the status of Jewish physicians in Germany. Their exodus, however, was by no means as sudden as that of their colleagues in Austria after its annexation to the German reich. When the great wave of German doctors came to Palestine in 1933 the Workers' Health Insurance Fund, like the rest of the Jewish community, enjoyed comparative prosperity. From 1933 to 1939 the number of physicians was increased from eighty to 312, of whom 138 were of German origin, twenty-nine from Austria and sixty-five from various other countries.

The Austrian physicians arriving during the past year have found the country in a disturbed rather than in a prosperous state. The highly specialized character of their training and the impossibility of transferring their capital have made their rehabilitation in a new country difficult. As but few new openings were available, physicians were sent temporarily to posts hitherto held by laymen, for which medical training is desirable but not necessary, such as those of assistants in laboratories and x-ray institutes and inspectors of sanitation in rural settlements.

Docent Rudolph Strisower has been appointed consultant to the Diagnostic Committee, which examines difficult cases at the Tel-Aviv Central Dispensary. Dr. Strisower was awarded many honors for his services as bacteriologist and epidemiologist in the Austrian army during the World War. After the armistice he entered the Vienna Infirmary and General Hospital as assistant to the specialist for diseases of the heart and blood vessels Professor Pal and later worked with Professor Wenckebach.

Docent Robert Lenk is in charge of x-ray work in the Kupat-Holim Hospital at Afoula and in its central dispensary in Haifa. He has published eighty-seven scientific papers and was director of the Roentgen Institute of the Vienna Workers' Sick Fund from 1928 to 1938.

Dr. Ernest Spira, who has had wide experience in orthopedic surgery in Prague, Vienna and Leipzig, is now working as orthopedic surgeon in the Tel-Aviv Central Dispensary.

Dr. Aria Rappaport, chemist and bacteriologist of the Vienna Hygiene Institute, has been added to the staff of the Beilinson Hospital.

Dr. Erich Nassau has been appointed chief of the pediatrics department at the Emek Hospital and inspector of children's institutions in the Valley of Jezreel. He is joint author with Prof. L. F. Mayer of a textbook on children's nutrition, was in charge of the pediatrics department of the Berlin Municipal Hospital and was director of a sanatorium for children with chronic diseases.

Dr. Karl Kawalek, who has been appointed resident gynecologist at the Emek Hospital, has had wide experience in this field as assistant to Professor Lorenz, Professor Novak and Docent Hidler.

Dr. Otto Tetzner, now consultant in pediatrics in the Tel-Aviv Central Dispensary, was first assistant in Professor Knoepfelmacher's children's clinic from 1920 to 1927 and thereafter pediatrician for the Vienna Workers' Sick Fund.

Prof. Walter Strauss was formerly professor of hygiene at the Berlin University and permanent adviser to the Hygiene Section of the League of Nations. In this capacity he was sent to various countries to investigate the effect of climatic conditions on work and fatigue. He has already been of inestimable assistance to Kupat Holim in the investigation of rural hygiene and sanitation problems. During an epidemic of typhoid in the Jordan Valley at Afikim a committee of experts, including Professor Strauss, was able by immediate action to check its spread. The committee flew by plane, as the roads were not safe for travel, and laboratory equipment was immediately sent to them. Invaluable aid was rendered by the government department of health, which made room for all patients in the government hospital at Haifa. Professor Strauss has recently been appointed hygienic adviser to the Industrial Hygiene Committee of the General Federation of Labor (Histadruth) in Palestine.

Prof. Bernhard Gottlieb, professor of dentistry of Vienna, is now consultant to the Tel-Aviv Dental Dispensaries. He is an honorary member of the British Royal Society, of the Allied Dental Council of America and of many other honorary societies in various countries. He has made important contributions to the etiology and treatment of pyorrhea, root canal work and other fields. He has already published the first part of his forthcoming book on dentistry in individual phases, the treatment of root canals.

Physicians entering the Kupat-Holim service regardless of their previous merits and standards have shown a willingness to adapt themselves to conditions in the country. They have been ready to supplement their European medical education by a special study of local endemic diseases. They have been ready to acquire a new language as well as to understand the physician-patient relationship in a workers' cooperative medical organization. This specific training has been provided in the clinics and hospitals of the organization, and their first appointment frequently finds them in rural dispensaries and even in labor camps in dangerous sections of the country.

The Hadassah Medical Organization has extended similar aid both by direct appointments and by offering facilities for study, observation and training in its hospitals and clinics.

During the past three years twenty-four physicians from Germany, Austria and latterly Italy have been appointed by Hadassah to its hospitals and affiliated departments. Among these is Prof. Enrico Emilio Franco, formerly head of the department of anatomy and histologic pathology at the Royal University of Pisa. Another recent appointment is that of Docent F. Mandel, author of 183 scientific papers, former assis-

tant in the Vienna General Infirmary and latterly head of the surgery department of the Canning-Childs Hospital.

New refugees are daily appearing. Among those who are known for their scientific work abroad and are not yet affiliated with medical institutions is the biochemist Prof. Harry Schaeffer, professor of internal medicine at the University of Breslau until 1933 and thereafter head of the department of internal medicine of the Breslau Jewish Hospital.

The following eminent physicians have taken up their residence in Palestine: the gynecologist Prof. Bernhard Zondek, the internists Prof. Hermann Zondek, Prof. S. G. Zondek, Docent Kleberg, Dr. Heller, Dr. Lewkowitz, Professor Citron and Professor Minz, the entomologist and helminthologist Prof. S. Adler, the pediatricians Prof. L. F. Mayer and Professor Rosenbaum, the radiologist Professor Halberstatter, the neurologist Professor Pappenheim and the gynecologist Professor Schonholtz.

The problem of assisting medical refugees is daily assuming larger proportions as letters continue to pour in from Jewish physicians in Italy and Czechoslovakia, Poland and Rumania.

The New Haifa Government Hospital

The new government hospital was officially opened by High Commissioner Sir Harold McMichael Dec. 22, 1938. This hospital, of 230 beds, is one of the largest in the country. The buildings are beautifully located on a site overlooking the Haifa Bay and the Carmel Range. They comprise (1) a main block of six stories containing wards and nurses' quarters, medical officers' quarters and kitchen and dining rooms, all facing the prevailing summer winds from the northwest but avoiding the sun's rays in the summer; (2) an operation, outpatient x-ray and laboratory block of three stories, also facing northwest but separated from the main building by a causeway to enhance free circulation of air from north to west; (3) an admission block, containing first aid rooms, offices and a pharmacy under the causeway; (4) a service block at ground level and a basement containing laundry, disinfection quarters, mortuary, chapel, garages and staff quarters, and (5) five one story isolation pavilions, separated from the main hospital, for patients with infectious diseases.

The hospital is open to all communities to the limit of its capacity. In addition to surgical, medical and maternity patients, it provides for all patients with the more serious infectious diseases from the town and districts of Haifa, Acre and Nazareth and in case of need even further north.

Medical Department of the Jewish National and University Library

The Jewish National and University Library, the largest in the Near East, with 350,000 volumes, owes its existence to the Russian physician Dr. Chasanowitch, who more than forty years ago conceived the idea of a Jewish National Library in Jerusalem. His collection formed the nucleus of the present university library.

It was the insight and the devotion of the American physician Dr. Julius Jarcho which transformed the medical department of the university library into an institution of vital importance for the medical progress of the country. For fifteen years Dr. Jarcho has not only been devoting himself to the development of the library but has succeeded in enlisting the aid and interest of a wide circle of friends and colleagues in America. Since 1925 hundreds of the most important periodicals and thousands of recent medical works have been sent to the library by the American Jewish Physicians' Committee, under the presidency of Dr. Nathan Ratnoff and with the active support of Dr. Emanuel Libman.

Apart from these extensive contributions, mention should be made of the large ophthalmic library donated by Professor Deutschmann, the collection of the Nobel Prize winner Barani, the collections of dental works sent by Drs. Wachtel, Misch and Kantorowitsch and the works on the history of medicine donated by Professor Libman and Dr. Friedenwald. The medical department now contains approximately 36,000 volumes and some 3,000 antiquated or less important works. Two hundred and fifty current periodicals are displayed in its reading room, and five branch libraries are being maintained by it in various parts of the country.

In 1929, the collections of the library were transferred to the new library building on Mount Scopus. In order to meet the requirements of physicians practicing in town, a reading room for periodicals and a reference library of some 1,200 volumes was established in the Nathan Straus Health Center and later in the Hadassah Hospital. Branch libraries have been opened by the medical department in Tel-Aviv, Haifa, Afoula, Tiberias and Petah-Tikva.

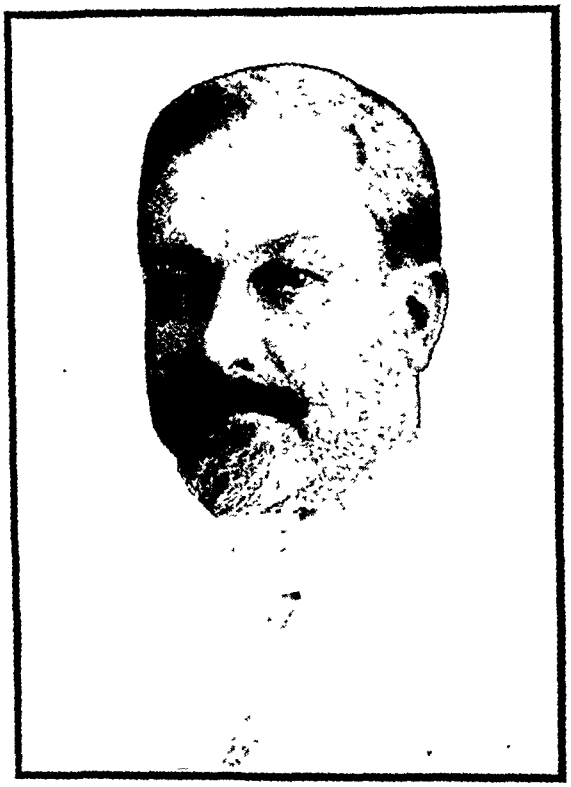
THE NETHERLANDS

(From Our Regular Correspondent)

Feb. 16, 1939.

International Congress of Malariology

At the International Congress of Malariology, held in the grand auditorium of the Institut Colonial, the minister of colonies and a representative of Queen Wilhelmina were present. Inaugural addresses were delivered by Professors Snyders, Grijns and Swellengrebel and Minister Welter. Some 500 physicians from Europe, Africa, America, the British Indies and the Netherlands Indies attended. The program included 114 reports on deficiency diseases, filarioses, yellow fever, antiplague vaccination, Leptospira, Trypanosoma, Glossina, Rickettsia, rabies and paludism.



The pathogenesis of filarioses was discussed by J. Rodhain. The penetration of the human organism by infectious larval filariae does not seem to be accompanied by any appreciable reaction, general or local. The eosinophilia of the blood which usually ensues seems to be independent of external clinical manifestations. The pathogenesis of the clinical symptoms remains obscure. Some of the morbid signs related to filariosis may be attributed to local irritation provoked by adult filariae, others to indirect reactions of an allergic or toxic nature, and still others to the presence of larval filariae. G. F. Stefanopoulo discussed recent advances in yellow fever research. The diagnosis of yellow fever has become possible through the application of serologic methods (the protection test), histopathologic methods (viscerotomy) and observation of the virus (inoculation of the monkey and the white mouse). The homogeneity of the amaril virus has been established. An exact delimitation of the zones of yellow fever on both continents has been made and, what is more, the presence of the virus, in the absence of Stegomyia, has been demonstrated in the South American jungle. The methods of prophylaxis have become more numerous. Anti-amaril vaccination can now be considered an effective preventive measure; the discovery of the attenuated virus by culture of embryonal tissues has made possible mass immunizations of populations which could not be protected by any other known means. The systematic fight against Stegomyia has produced such favorable results that campaigns of this sort are now felt to be imperative for the protection of urban populations.

Georges Lavier, discussing the antiglossina campaign, said that an effective campaign against Glossina in a particular region cannot be initiated without a sound knowledge of the character and biology of the local species. Major measures are directed against the vegetation considered to be the breeding place of Glossina. Minor measures include the capture of the flies by means of nets or traps. Biologic prophylaxis envisages the utilization as parasites on the pupa of creatures that prey on Glossina.

Deaths

Alexander Lambert ⊕ President of the American Medical Association 1919-1920, died in New York at the Doctors' Hospital May 9, aged 77. Dr. Lambert was born in New York Dec. 15, 1861, the son of Dr. Edward W. and Martha W. Lambert. He received his bachelor of arts degree from Yale University in 1884, the bachelor of philosophy degree in 1885 and the M.D. degree from the College of Physicians and Surgeons of Columbia University in 1888. The bachelor of philosophy degree was in association with research under Dr. Russell H. Chittenden. After two years of study in Europe, Dr. Lambert was associated with Dr. T. Mitchell Prudden and Dr. William H. Park in the investigation of tetanus and diphtheria antitoxin. Early in his career he began teaching, becoming professor of clinical medicine at Cornell University Medical College, holding that position from 1898 to 1931. He was also assistant bacteriologist in the New York Department of Health from 1894 to 1901 and attending physician in Bellevue Hospital from 1894 to 1933.

Throughout his career Dr. Lambert took great interest in the work of organized medicine, serving as president of the Medical Society of the State of New York, as a member of the House of Delegates of the American Medical Association in 1911, third vice president in 1909. He was appointed a member of the Judicial Council in 1911 and became chairman in 1912, holding that position until his election to the position of President-Elect in 1918. He was also chairman of the Section on Practice of Medicine 1903-1904. He served in New York City on the Mayor's Committee on Narcotic Addiction in 1927 and as a member of a state commission on the same subject. His memberships in medical societies included the Association of American Physicians, the Harvey Society, the American Association for the Advancement of Science, the American Heart Association and several other local medical bodies. In 1917 he was appointed a Major in the Medical Corps and sent to France, where he remained until the Armistice, serving in France also as medical head of the American Red Cross.

ALEXANDER LAMBERT, M.D., 1861-1939

Early in his career he became closely associated with former President Theodore Roosevelt, acting for many years as his personal physician and also accompanying him on hunting and fishing trips. In 1919, following the death of Theodore Roosevelt, Dr. Lambert became the director of the Roosevelt Memorial Association. Dr. Lambert is also credited with having been instrumental in maintaining Gen. William C. Gorgas as director of the sanitary work during the building of the Panama Canal after an attack had been made on the work of General Gorgas by some of the lay officials in charge of the building of the Canal.

Throughout his career Dr. Lambert gave special attention to problems of alcoholic and narcotic addiction and to diseases of the heart. He was the author of numerous contributions to medical periodical literature dealing with these subjects. Dr. Lambert was widely known as a distinguished leader in the field of medicine, as an inspiring organizer and as an influential physician.

Richard Clarke Cabot ⊕ widely known as a physician, teacher and author, died in Boston, May 8, after a long illness. Dr. Cabot was born in Brookline, Mass., the son of James Elliott Cabot and Elizabeth Dwight Cabot, on May 21, 1868. His father was an overseer of Harvard University and was noted as the biographer of Ralph Waldo Emerson. After graduation from Harvard in 1889, where he won honors in the classics and in philosophy and election to Phi Beta Kappa, Dr. Cabot continued his studies in Harvard Medical School and graduated in 1892. He became assistant in medicine in Harvard Medical School in 1899, instructor in 1903, assistant professor in 1908, professor in 1918 and, since 1933, has been professor emeritus.

Dr. Cabot's interest in ethics and philosophy persisted throughout his life; he lectured on logic in Harvard in 1903, and was appointed professor of social ethics in 1920, holding that position until 1934.

As part of his medical career, Dr. Cabot became physician to the Outpatient Department of the Massachusetts General Hospital in 1898, and was also consultant in the Massachusetts General Hospital, New England Hospital for Women, the Westboro School for Boys, the Lancaster School for Girls, the Brockton Hospital and the Sturdy Memorial Hospital of Attleboro. He was also a former visiting physician to the Channing Home, consulting physician to the Massachusetts Eye and Ear Infirmary and chief of staff at the Mount Sinai Hospital.

During the World War, Dr. Cabot served as a major in the Medical Corps at a Bordeaux base hospital, remaining there from July 1917 to February 1919, except for a period of five months when he was associated with the Red Cross Service in Paris. He was commissioned Lieutenant Colonel Nov. 6, 1918, and honorably discharged in February 1919.

As for the social side of his interests, he was president of the National Conference of Social Work in 1931 and president of the Massachusetts Anti-Saloon League in 1931-1933; he was awarded the gold medal by the National Institute of Social Science in 1931.

The University of Rochester bestowed on him the LL.D. degree in 1930, and Syracuse University awarded him the L.H.D. degree in 1934.

In the American Medical Association, Dr. Cabot was chairman of the Section on Practice of Medicine from 1904 to 1905 and a member of the House of Delegates in 1907 and in 1915.

Early in his career, Dr. Cabot attracted wide public attention by his attitudes in relationship to the social aspects of medical care. In 1913, he pointed out that there were far too many doctors, and urged reorganization of medicine for group practice, with the suggestion that, since the University of California had been able to provide students with medical care for $5 a year, it should be possible to do the same for all people. He was also widely noted for the statement that out of 400 diseases only seven were curable by drugs and five by inoculations. Moreover, his statement to the effect that the vast majority of diagnoses were wrong as based on the results of postmortem examinations, made many years ago, was repeatedly quoted in the press.

Perhaps Dr. Cabot was most widely known for writings, particularly in the field of social welfare. These publications included "Social Service and the Art of Healing," 1909; "What Men Live By," 1914; "The Rewards and Training of a Physician," 1917; "Social Work," 1919; "Adventures on the Borderlands of Ethics," 1926; "The Meaning of Right and Wrong," 1933, and "Christianity and Sex," 1937. Particularly known to the medical profession are his writings in medicine, including "Clinical Examination of the Blood," 1896, of which five editions were issued, and his work on "Physical Diagnosis," 1901, of which ten editions were issued. Well known also were his books on "Case Teaching in Medicine," 1906, reprinted in more recent years in a special series in the *New England Journal of Medicine*, and "Differential Diagnosis," 1911. His last public appearance was in the New York Herald Tribune Forum, 1938.

Dr. Cabot will long be remembered for his philosophy and as a leader in stimulating social habits of thought.

Frank Parsons Norbury ⊕ Jacksonville, Ill.; Long Island College Hospital, Brooklyn, 1888; secretary of the Section of Neurology and Medical Jurisprudence, 1893-1894, and member of the House of Delegates of the American Medical Association in 1904; past president of the Morgan County Medical Society; fellow of the American College of Physicians and member of the American Psychiatric Association; past president and secretary of the Mississippi Valley Medical Association; professor of internal medicine, St. Louis College of Physicians and Surgeons, 1895-1896, and professor of nervous and mental diseases, Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904-1908; alienist, state board of administration, 1911-1913; superintendent of the Kankakee (Ill.) State Hospital, 1909-1911; acting medical director of the National Committee for Mental Hygiene during the World War; president and medical director of the Norbury Sanitarium; aged 75; died, March 14, of coronary thrombosis.

Noble Murray Eberhart ⊕ Chicago; Bennett Medical College, Chicago, 1894; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; director of the x-ray laboratory and head of the department of physiological therapeutics, Loyola University School of Medicine, 1911-1913, and professor of electrophysics, Post-Graduate Medical School, 1902-1905; at various times professor and head of the department of electrotherapy, American College of Medicine and Surgery, Medical Department of Valparaiso University, and Chicago College of Medicine and Surgery, Medical Department of Valparaiso University; president of the North Shore Branch, 1912-1913, and member of the Council, Chicago Medical Society, 1913-1915; author of "Manual of High Frequency Currents," which passed through eight editions; aged 68; died, February 9, of epithelioma of the left hand with metastasis.

Jose Guillermo Lewis, Colon, Republic of Panama; Georgetown University School of Medicine, Washington, D. C., 1923; member of the Medical Association of the Isthmian Canal Zone; fellow of the American College of Surgeons; at one time instructor of surgery at his alma mater; formerly chief surgeon and chief of staff, Eastern Dispensary and Casualty Hospital; chief of the surgical service, including obstetrics and gynecology, Amador Guerrero Hospital; aged 40; died, February 12.

Samuel Robert Slaymaker ⊕ Chicago; Rush Medical College, Chicago, 1892; clinical professor of medicine at his alma mater; past president of the Chicago Society of Internal Medicine; president and attending physician to the Washington Boulevard Hospital; associate attending physician to the Presbyterian Hospital; for many years on the attending staff of the Cook County Hospital; served during the World War; aged 74; died, May 3, of carcinoma of the pancreas.

George Charles Kreutz, Detroit; Washington University School of Medicine, St. Louis, 1924; member of the Michigan State Medical Society and American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; surgeon in charge, division of otolaryngology, Henry Ford Hospital; aged 42; died, February 1, of pulmonary embolus following an operation for hernia.

Joseph Thompson McKinney ⊕ Roanoke, Va.; Medical College of Virginia, Richmond, 1912; member of the American Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; served during the World War; on the staff of the Lewis-Gale Hospital; aged 49; died, February 3, of carcinoma of the prostate with metastasis to the liver and lungs.

Paul Eugene Lineback, Emory University, Ga.; Drake University Medical Department, Des Moines, Iowa, 1911; professor of micro-anatomy and neuro-anatomy at the Emory University School of Medicine; fellow of the American College of Physicians; member of the American Association of Anatomists; co-author of "Anatomy of the Rhesus Monkey"; aged 59; died, February 28.

George Goodhue ⊕ Dayton, Ohio; Dartmouth Medical School, Hanover, N. H., 1880; University of the City of New York Medical Department, 1880; past president of the Montgomery County Medical Society; fellow of the American College of Surgeons; formerly health officer; consulting surgeon to the Miami Valley Hospital; aged 85; died, February 25.

Stephen H. Knight ⊕ Detroit; New York Homeopathic Medical College, New York, 1886; fellow of the American College of Surgeons; at one time assistant professor of surgery at the Detroit College of Medicine and Surgery; for many years on the staff of the Grace Hospital; aged 76; died, February 9, of arteriosclerotic heart disease.

Page D. Barlow, McMechen, W. Va.; Baltimore Medical College, 1895; member of the West Virginia State Medical Association; past president of the Marshall County Medical Society; aged 65; on the staff of the Reynolds Memorial Hospital, Glendale, where he died, February 23, of diabetes mellitus and lobar pneumonia.

Frank Wallace Curtis, Stewartsville, N. J.; Long Island College Hospital, Brooklyn, 1892; member of the Medical Society of New Jersey; on the staff of the Easton (Pa.) Hospital; aged 73; died, February 9, in the King's Daughters' Hospital, Portsmouth, Va., of cerebral hemorrhage and hemiplegia.

Thomas J. Farley, Amherstdale, W. Va.; University of Louisville (Ky.) Medical Department, 1913; member of the West Virginia State Medical Association; formerly county health officer; aged 54; died, February 18, in the Mercy Hospital, Logan, following an operation for a ruptured appendix.

Harry Cullen Kariher, Champaign, Ill.; Rush Medical College, Chicago, 1903; member of the Illinois State Medical Society; past president of the Champaign County Medical Society; served during the World War; aged 59; on the staff of the Burnham City Hospital, where he died, February 5.

Robert Caldwell McChord, Lebanon, Ky.; Louisville (Ky.) Medical College, 1875; member of the Kentucky State Medical Association; fellow of the American College of Surgeons; formerly president of the board of education and bank president; aged 87; died, February 19, of arteriosclerosis.

Robert Christie Kemp, Baton Rouge, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1900; fellow of the American College of Surgeons; visiting surgeon to the Baton Rouge Hospital and Our Lady of the Lake Sanitarium; aged 65; died, February 19, of pneumonia.

Gaston Louis Gaudet, Lutcher, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1904; member of the Louisiana State Medical Society; aged 59; died, February 7, in the Hotel Dieu, Sisters' Hospital, New Orleans, of auricular fibrillation and pleurisy with effusion.

James McFaddin Dick ⊕ Salisbury, Md.; University of Maryland School of Medicine, Baltimore, 1895; fellow of the American College of Surgeons; on the staff of the Peninsula General Hospital; aged 67; died, February 17, of cerebral hemorrhage and arteriosclerosis.

Edwin Archer Gerhart, Seattle; Hahnemann Medical College and Hospital of Philadelphia, 1901; member of the Washington State Medical Association; served during the World War; aged 60; died, February 28, in a local hospital of carcinoma of the liver.

Vernon Sylvester Fildes, Olney, Ill.; Washington University School of Medicine, St. Louis, 1905; member of the Illinois State Medical Society; aged 57; died, February 4, in the Olney Sanitarium, of bronchopneumonia and cerebral hemorrhage.

Walter Pearre, Waynesboro, Pa.; Bellevue Hospital Medical College, New York, 1884; Hahnemann Medical College and Hospital of Philadelphia, 1885; aged 77; died, January 16, at the Waynesboro Hospital, of gastric ulcer with pyloric stenosis.

Richard Lodwick Gray, Clayton, N. Y.; Bellevue Hospital Medical College, New York, 1898; member of the Medical Society of the State of New York; aged 68; died, January 28, of carcinoma of the urinary bladder with metastases to the breast.

James M. Fenton, Baltimore; University of Virginia Department of Medicine, Charlottesville, 1894; member of the Medical Society of Virginia; formerly coroner of the central district; aged 70; died, February 17, of cardiac decompensation.

Frederick Yingling Allen, St. Petersburg, Fla.; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1898; formerly associate professor of histology at his alma mater; aged 65; died, February 26.

Francis Earle Briggs, Ludlow, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; member of the Illinois State Medical Society; aged 56; died, February 2, of carcinoma of the stomach.

William Clarkson Waggoner, New York; Miami Medical College, Cincinnati, 1903; formerly on the faculty of the Long Island College Hospital, Brooklyn; served during the World War; aged 57; died, January 27, in Ossining.

Daniel James Leo Harrington ⊕ Boston; Tufts College Medical School, Boston, 1910; on the staffs of the Boston City Hospital and the Carney Hospital; aged 52; died, February 20, in St. Francis Hospital, Miami Beach, Fla.

Martin Cole, Hainesville, N. J.; Harvard University Medical School, Boston, 1873; aged 89; died, February 25, in the Newton (N. J.) Memorial Hospital, of chronic myocarditis and fracture of the hip received in a fall on the grass.

William Edgar Fahrney ⊕ Broadway, Va.; University of Maryland School of Medicine, Baltimore, 1897; aged 65; died, February 13, at the University Hospital, Charlottesville, of arteriosclerosis, cerebral thrombosis and pneumonia.

Clarence Kelsay, Evansville, Ind.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; on the staff of the Protestant Deaconess Hospital; aged 62; died, February 8, of pneumonia with hypertension.

Joseph Hall Jones, Baltimore; University of Alabama School of Medicine, 1912; served during the World War; acting assistant surgeon, U. S. Public Health Service; aged 52; died, February 20, of coronary thrombosis.

James Francis Bowen, Hinsdale, Mass.; University of Vermont College of Medicine, Burlington, 1911; served during the World War; aged 60; died, February 21, in St. Luke's Hospital, Pittsfield, of cerebral hemorrhage.

Edward Daniel Hartnett, Boston; Harvard University Medical School, Boston, 1898; member of the Massachusetts Medical Society; served during the World War; aged 64; died, February 13, of cerebral hemorrhage.

James Asbury Harper ⊕ Greenfield, Iowa; Bellevue Hospital Medical College, New York, 1896; formerly secretary of the Adair County Medical Society; aged 71; died, February 9, of arteriosclerosis and coronary occlusion.

Thomas Archibold McIntyre, Colorado Springs, Colo.; Gross Medical College, Denver, 1902; member of the Colorado State Medical Society; on the staff of St. Francis Hospital; aged 52; died, January 24, of diphtheria.

Marcus S. Lemlich, Brooklyn; New York Medical College and Flower Hospital, New York, 1914; on the staffs of the Unity Hospital and the Cumberland Hospital; aged 52; died, January 18, in the Mount Sinai Hospital.

Frank G. Emerson, Wellington, Kan.; State University of Iowa College of Medicine, Iowa City, 1885; member of the Kansas Medical Society; aged 78; died, February 12, of an injury received in a fall in a bathtub.

Alfred M. Houston ⊕ Joliet, Ill.; Hahnemann Medical College and Hospital, Chicago, 1904; on the staffs of the Silver Cross Hospital and St. Joseph's Hospital; aged 63; died, February 9, of sarcoma of the maxilla.

Mecislaus Stanley Kreda, National Military Home, Ohio; Wayne University College of Medicine, Detroit, 1933; on the staff of the Veterans Administration Facility; aged 35; died, February 21, of pulmonary embolism.

Rudolph J. Maas ⊕ Houghton, Mich.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1880; formerly on the staff of St. Joseph's Hospital, Hancock; aged 83; died, February 7, of acute coronary disease.

John I. McCormick, Yazoo City, Miss.; Jefferson Medical College of Philadelphia, 1899; member of the Mississippi State Medical Association; on the staff of the King's Daughters Hospital; aged 67; died, January 23.

Joseph H. McGauhey ⊕ White Cloud, Kan.; Missouri Medical College, St. Louis, 1888; bank president; formerly member of the school board; aged 77; died, February 8, in St. Joseph's Hospital, St. Joseph, Mo.

Ira Lincoln Fetterhoff, Baltimore; University of Maryland School of Medicine, Baltimore, 1885; Hahnemann Medical College and Hospital of Philadelphia, 1886; aged 74; died, February 25, of diabetes mellitus.

Sheldon S. De Lancey, Williamsport, Ind.; Hahnemann Medical College and Hospital, Chicago, 1882; member of the Indiana State Medical Association; county health officer; aged 78; died, February 7, of senility.

Bruce D. Campbell, Dearborn, Mich.; Detroit College of Medicine and Surgery, 1915; chief physician and surgeon of hospitals of the Ford Motor Company's plants; aged 45; died, March 20, of heart disease.

George Benjamin Hulburd, Jericho, Vt.; University of Vermont College of Medicine, Burlington, 1885; member of the Vermont State Medical Society; aged 77; died, February 4, of carcinoma of the rectum.

Earle McEwen ⊕ Mason City, Iowa; Hahnemann Medical College and Hospital, Chicago, 1881; past president of the Cerro Gordo County Medical Society; aged 81; died, February 17, of coronary thrombosis.

Christopher C. Gray, Batesville, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1888; member of the Arkansas Medical Society; aged 79; died, February 17, of hypostatic pneumonia.

Joseph B. Kepler Evans, McGuffey, Ohio; American Eclectic Medical College, Cincinnati, 1889; member of the Ohio State Medical Association; aged 74; died, February 10, of pulmonary tuberculosis.

Alford Comer Knight, Jacksonville, Fla.; Medical College of the State of South Carolina, Charleston, 1911; member of the Florida Medical Association; formerly a pharmacist; aged 63; died, February 11.

Willard Blossom Segur ⊕ Ware, Mass.; Dartmouth Medical School, Hanover, N. H., 1892; on the staff of the Mary Lane Hospital; aged 73; died, January 27, in the Deaconess Hospital, Boston.

Oscar Newton Lightner, Laredo, Texas; Washington University School of Medicine, St. Louis, 1905; served during the World War; aged 57; died, February 13, in the Nix Hospital, San Antonio.

Wladimir Feodor de Niedman, Los Altos, Calif.; Howard University College of Medicine, Washington, D. C., 1884; veteran of the Spanish-American War; aged 84; died in January in San Francisco.

James Perry Houston, Traverse City, Mich.; Chicago Medical College, 1889; member of the Michigan State Medical Society; aged 78; died, February 27, in the Grand Traverse County Hospital.

Silas Offen Witherbee, Middletown, Ky.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1867; formerly bank president; aged 92; died, January 2.

Septimus Jordan, Richburg, S. C.; Medical College of the State of South Carolina, Charleston, 1911; member of the South Carolina Medical Association; aged 51; died, February 15, of arthritis.

James Thomas Justice, Kernersville, N. C.; North Carolina Medical College, Davidson, 1904; for many years member of the school board; aged 65; died, February 15, of carcinoma of the prostate.

Henry Eben Hunt, Roodhouse, Ill.; Northwestern University Medical School, Chicago, 1896; aged 66; died, February 8, in Our Saviour's Hospital, Jacksonville, of carcinoma of the rectum.

Charles Holt Forbes, Athol, Mass.; New York Homeopathic Medical College, New York, 1883; aged 79; died, February 7, in the Massachusetts Masonic Hospital, Shrewsbury, of myocarditis.

B. Clinton Marsh, Livingston, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1886; member of the State Medical Association of Texas; aged 78; died, February 22.

Joseph Anton Denkinger, Brookline, Mass.; Vermont Medical College, Rutland, 1889; aged 76; died, February 27, in Boston of diabetes mellitus, cerebral arteriosclerosis and chronic myocarditis.

Marriages

EDWARD DUNNER, Brooklyn, to Miss Reichel Connor of Pittston, Pa., March 19.

JAMES L. SEIBOLD to Miss Margareate Stewart, both of Birmingham, Ala., April 29.

THOMAS E. BRADLEY to Miss Evelyn Mashburn, both of Fitzgerald, Ga., in April.

JOSEPH A. HESCH, Aldan, Pa., to Miss Marie B. McGowan of Philadelphia, April 29.

THOMAS Y. DORWART to Miss Ellen Vaughn, both of Lexington, Neb., February 14.

BENJAMIN HARTWELL BOYD JR. to Miss Margaret McCarty, both of Atlanta, Ga., April 29.

JOSEPH HELMS FARROW, New York, to Miss Florence Skinner of Kansas City, Mo., April 28.

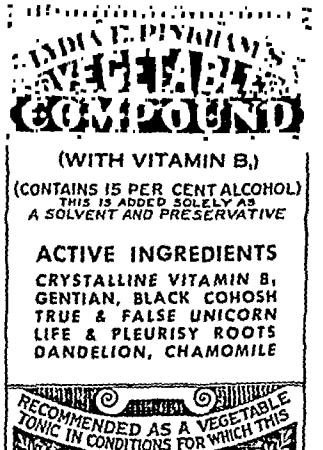
JOHN GOODRICH SMITH, Rocky Mount, N. C., to Miss Mary Lillian Wagner of Warrenton, April 25.

WILLIAM EDGAR WADDELL, Lexington, Va., to Miss Joan Thompson of St. Johns, Newfoundland, recently.

DANIEL O'CONNELL SAYERS, Waterbury, Conn., to Miss Mary Adams Oliver of Mount Olive, N. C., in Goldsboro, N. C., in April.

Bureau of Investigation

SIXTH LABEL FOR LYDIA E. PINKHAM'S VEGETABLE COMPOUND FINALLY BARES FORMULA



Actual Ingredients Exposed for the First Time

The Bureau of Investigation called attention to a new label for "Lydia E. Pinkham's Vegetable Compound" in THE JOURNAL Dec. 17, 1938. The label which was discussed at that time indicated that a new ingredient—vitamin B_1—had been added and that the name of the preparation had been changed to "Lydia E. Pinkham's Vegetable Compound (With Vitamin B_1)." This label is reproduced here, along with an even newer label on which the active ingredients are listed.

The previous article discussed whether or not vitamin B_1 was indicated in any appreciable percentage of those who took this preparation. At the same time attention was called to the fact that there was probably nothing harmful in its addition to the Compound. Nevertheless it is a question whether or not a preparation containing 15 per cent alcohol would be useful to persons deficient in vitamin B_1 and who might take this remedy for the purpose of obtaining additional vitamin B_1.

In the previous article four older labels for this preparation were reproduced. The first label appeared before the enactment of the Food and Drugs Act of 1906, as amended, on which the preparation was claimed to be "A Sure Cure for Prolapsus Uteri, or Falling of the Womb, and All Female Weaknesses." The next three labels comprised modifications of this claim in accordance with the act of 1906. In the first of these the phrase "A Sure Cure" was deleted. In the second this wording was replaced by the phrase "Recommended for the Treatment of Non-Surgical Cases of Weaknesses and Disorders of the Female Generative Organs, Catarrhal Leucorrhea and Irritation." The final label which was issued under the act of 1906 merely contained the statement that the preparation was "Recommended as a Vegetable Tonic in Conditions for Which This Preparation is Adapted." As Dr. Arthur J. Cramp pointed out in an article in *Hygeia* "This statement is about as informative as it would be to say that 'For Those Who Like This Sort of Thing, This Is the Sort of Thing That Those People Like.'"

The label which is reproduced above appeared on a bottle purchased in the early part of 1939. The label reproduced at the right is even more recent, and declares all of the active ingredients, in accordance with the Federal Food, Drug and Cosmetic Act.

According to Section 502(e) of the Federal Food, Drug and Cosmetic Act a drug shall be deemed to be misbranded:

"If it is a drug and not designated solely by a name recognized in an official compendium unless its label bears (1) the common or usual name of the drug, if such there be; and (2) *in case it is fabricated from two or more ingredients, the common or usual name of each active ingredient,* including the quantity, kind, and proportion of any alcohol, and also including whether active or not, the name and quantity or proportion of any bromides, ether, chloroform, acetanilid, acetphenetidin, amidopyrine, antipyrine, atropine, hyoscine, hyoscyamine, arsenic, digitalis, digitalis glucosides, mercury, ouabain, strophanthin, strychnine, thyroid, or any derivative or preparation of any such substances, contained therein: Provided, That to the extent that compliance *with the requirements of clause (2)* of this paragraph is impracticable, exemptions shall be established by *regulations promulgated by the Secretary.*"

The second label reproduced in this article appears on the product as it is purchased over the counter today. In accordance with the stipulations quoted above, this label includes a list of the active ingredients. Thus, for the first time in the many years that this preparation has been on the American market, a purchaser is informed as to the nature of the product. Granted that the meaning of these various names of drugs is not particularly informative to the general public, nevertheless the ingredients are actually disclosed. Now agencies interested in keeping the public informed can call attention to the ingredients and their significance in modern therapeutics. There follows herewith a brief consideration of the ingredients listed on the label of Lydia Pinkham's Compound. The phrases which appear in quotation marks in the paragraphs below are taken from the present edition (or previous editions, in cases of those drugs which are no longer included in the present edition of the U. S. P. or N. F.) of the "Epitome of the U. S. P. and N. F." (A. M. A. Press).[1]

Crystalline vitamin B_1 is admittedly useful in cases in which there is a deficiency of this vitamin. Since the public buys the Pinkham preparation without consulting a physician, it is difficult to know just how people are able to determine that they have a need for this vitamin. Even granting such a need, there is no occasion for taking this drug, which is available in pure form and which is available in many foods, in a solution containing 15 per cent alcohol.

Gentian. The latest edition of the United States Pharmacopeia includes this item. It is "probably the most widely used of the simple bitters."

Black cohosh. This drug appears in the most recent edition of the National Formulary under the name Cimicifuga. It is "a 'domestic medicine' that has been tried as a stomachic, antispasmodic, aphrodisiac, diaphoretic, diuretic and expectorant, but which *has not been found to possess definite value.*"

True unicorn. This drug appears in the latest edition of the National Formulary under the name Aletris and is a root which is "used in proprietary 'female remedies' *without evidence of value.*"

False unicorn. This drug appears in the latest edition of the National Formulary under the name Helonias and has been stated to be an "ingredient of 'female remedies'; *without established value.*"

Liferoot. This drug no longer appears in the official compendiums but was included in the 1926 edition of the National Formulary under the name Senecio and has been said to have been used by the North American Indians for healing wounds. "It has been used in a variety of conditions, but *it is entirely superfluous.*"

Pleurisy root. This drug was also last heard of officially in the 1926 edition of the National Formulary and has been described as "an obsolete domestic remedy for pleurisy, also used as a diaphoretic. *Probably without value.*"

Dandelion. This appears in the present edition of the National Formulary under the title Taraxacum. It "has been used as a bitter tonic (without advantage over gentian) and is a mild laxative in habitual constipation (inferior to drugs like cascara sagrada); has no specific action on the liver."

Chamomile. This drug appears in the latest edition of the National Formulary under the title Matricaria and is said to be "popularly used as a bitter, an aromatic tea or a *poultice;* effects, if any, are due mainly to *hot water.*"

With the exception of the crystalline vitamin B_1, therefore, it is not even necessary to know the quantity of the ingredients to surmise that the Compound is not of any established value beyond whatever virtures may be attributed to the various bitters.

The failure to establish any value scientifically, however, does not seem to have much effect on the current advertising for this preparation. Here reproduced is a recent advertisement entitled "Women in Your 40's Need Not Lose Charm!" The implica-

1. Italics ours.

tion is that this Compound will prevent, or at least alleviate, the symptoms of the menopause. Scientifically the modern effective method of treating such symptoms is to supply the deficient hormone, which, of course, is not contained in this Compound.

WOMEN IN YOUR 40's

Need Not Lose Charm!

Here's good advice for a woman during her change (usually from 38 to 52), who fears she'll lose her appeal to men, who worries about hot flashes, loss of pep, dizzy spells, upset nerves and moody spells.

Just get more fresh air, 8 hrs. sleep and if you need a reliable "WOMAN'S" tonic take Lydia E. Pinkham's Vegetable Compound, made *especially for women*. It helps Nature build up physical resistance, thus helps give more vivacity to enjoy life and assist calming jittery nerves and those disturbing symptoms that often accompany change of life.

For free trial bottle tear this out and *send with* name and address to Lydia E. Pinkham Medicine Co., 973 Cleveland St., Lynn, Mass.

Pinkham's is WELL WORTH trying.

Lydia E. Pinkham's

VEGETABLE COMPOUND

There is not an iota of scientific evidence to support the recommendation of this mixture for the treatment of the symptoms of the menopause. It remains to be seen just what limits will be placed on this type of advertising in the near future. Progress has been made, but still more progress is necessary if the public is to be protected against the blandishments of "patent medicine" promoters.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DIAGNOSIS AND TREATMENT OF TABES

To the Editor:—1. What are the minimal manifestations on which a diagnosis of tabes dorsalis can be made? 2. Is an untreated tabes with negative spinal fluid a burned out tabes that requires no treatment? 3. What are the criteria for cessation of treatment in a case of tabes?

M.D., New York.

ANSWER.—1. It is difficult to say what are the minimal manifestations which would justify a diagnosis of tabes dorsalis. It would be well to have a positive spinal fluid associated with some pupillary changes and diminution of the deep tendon reflexes of the lower extremities. In the absence of a positive spinal fluid there should certainly be definite evidence to physical examination of disease of the posterior nerve roots in a patient diagnosed as having syphilis. The Cooperative Clinical Group (*Arch. Dermat. & Syph.* **38**:692 [Nov.] 1938) lists the following subjective and objective symptoms as of diagnostic value: diplopia, neuritic pain, reduced libido and potentia, gastrointestinal or laryngeal crises, paresthesia of the hands and feet, headache, dizziness, vertigo, ataxia, failing vision, incontinence, girdle sensation, Argyll Robertson pupils, fixed pupils, irregular pupils, anisocoria, reduction of the deep reflexes, reduction of pain sense, hyperesthesia, heat and cold changes, ataxia and incoordination.

2. It would be unwise to consider an untreated tabes with a negative spinal fluid as a burned out tabes. Such a patient should be submitted to at least the minimum standard treatment for the cure of syphilis, as advised by the Cooperative Clinical Group, provided age and physical condition will permit.

3. The age of the patient, his symptoms and the benefits derived from treatment should be used as criteria in determining the duration of treatment for tabes. The Cooperative Clinical Group survey mentioned has shown that routine therapy in the form of at least two courses of arsphenamine of eight injections and from twelve to fifteen injections of a bismuth preparation will reverse the reaction of the spinal fluid in many cases of tabes dorsalis. When examination of the spinal fluid shows that treatment as just described has not made any material change in the spinal fluid and where there is no material improvement in the clinical aspects of the disease, the patient should be given the advantage of supplemental or auxiliary treatment. If the routine is to produce the most satisfactory result, it must consist of more than twenty injections of arsphenamine and twice as much of a bismuth preparation. Intraspinal therapy is most efficient when a minimum of seven intraspinal treatments is given in conjunction with the routine treatment. When tryparsamide is employed, at least thirty injections of tryparsamide and thirty injections of a bismuth preparation should be given to a course, although the most satisfactory results are noted among patients who receive 100 or more injections each of tryparsamide and of bismuth preparations. If malaria therapy is used, a patient should undergo not less than eight "chills" or satisfactory rises of temperature.

NEPHRITIS AND PREGNANCY

To the Editor:—A primipara aged 28 was first seen in January 1938 with a three and one-half months gestation and no abnormalities on physical examination. The blood pressure was 125/75. In February it was 155/85 and in April 194/110 with 2 plus albumin in the urine, no casts, but occasional white cells. With bed rest and sedatives the blood pressure dropped to 165/90 but soon rose again. Finally the urine showed 4 plus albumin (end of May) and she was brought to a hospital and labor was induced by insertion of a Vorhees bag. While the bag was expelled, the cord prolapsed. Version and extraction of a 5½ pound (2,500 Gm.) baby could not save its life. The patient had a thrombophlebitis with uneventful recovery. Two months after delivery her blood pressure was 140/90, the urine was normal and she felt fine. At no time was there headache or precordial distress—only edema of the face and legs. She is anxious to know whether she could have another baby and when. Would two years' waiting have any bearing on a recurrence during the next pregnancy? Provided the blood chemistry is negative at present and kidney function tests (Mosenthal and phenolsulfonphthalein) good, could pregnancy be contemplated at once or never at all? M.D., Minnesota.

ANSWER.—The clinical history presented is typical of preexistent renal disease exacerbated by pregnancy. A true "low reserve kidney," such as this case presents, is perhaps the most significant of all the forms of renal and hypertensive disorders found in obstetric medicine. It is the type most frequently ignored until irreparable damage is done. The nephritides as they occur in pregnancy are best classified under four groups: type A, the simple nephrosis of pregnancy; type B, eclampsia or eclamptic intoxication; type C, preexistent renal and/or hypertensive disease exacerbated by pregnancy, and type D, coincident nephritis. Type A is characterized by a relatively late onset, profuse proteinuria, moderate hypertension, a good immediate prognosis and remarkably rapid and complete recovery after the termination of pregnancy. Eclampsia need not be discussed here. Coincident nephritis includes that small group of cases in which nephritis occurs in pregnant women for etiologic reasons wholly independent of the pregnant state: acute infective nephritis, mercury bichloride nephrosis, and so on (Adair, F. L., and Stieglitz, E. J.: Obstetric Medicine, Philadelphia, Lea & Febiger, 1934, chapter XXVIII).

Preexistent nephritis, such as unquestionably existed in the present case, is frequently unrecognized and silent until the increasing stresses and renal burden of pregnancy precipitate evidences of renal incompetence. The term "low reserve kidney," if strictly applied, obviously described just such a situation. The renal functional capacity is adequate for the ordinary load of renal work, but there is depletion of the reserve for the extra effort involved in the secretion of the greatly augmented metabolic débris of pregnancy. These stresses and other factors then incite an exacerbation of the renal injury. It is most important to keep in mind that much of the exacerbation of the renal injury persists permanently after the pregnancy in these cases. The renal functional reserve is usually notably lower after such an experience than before. Thus the risk in future pregnancies becomes increasingly great and the likelihood of obtaining a living infant increasingly remote.

Characteristic of this type of nephritis is the onset of hypertension early in the pregnancy. A useful and practical axiom is that the earlier in pregnancy hypertension and/or proteinuria appear the lower is the renal reserve. The longer such pregnancies continue, the greater the irrevocable renal damage and the poorer the ultimate prognosis for the patient. In those carried to fetal viability, or as long as possible, the future course

is usually downhill. Rapidly progressive hypertensive arterial disease is frequently initiated by pregnancy in these women. In such the prognosis is poor. Fetal mortality is close to 60 per cent even with the most conservative management.

It is notable that two months post partum this patient still has a borderline hypertension of 140/90 (age 28). The absence of protein from the urine is an utterly worthless criterion of her renal functional capacity. So also would be a present "negative blood chemistry" (blood constitutents at normal concentration). Increases in the concentration of the nonprotein nitrogenous metabolites in the blood occur only when actual renal decompensation exists. The patient's renal function appears to be adequate at present (under the present loads) but the depleted reserve would permit of renal failure if and when the load is increased, as with another pregnancy. Only careful evaluation of the patient's renal function reserve can tell what her margin of safety is. Stress tests such as the concentration procedure are of greater value here than the phenolsulfonphthalein or urea clearance tests.

The decision to deprive a woman of the privilege of bearing children must never be taken lightly. Therefore great care and thorough study are required before such questions can be adequately answered. In the present instance the following suggestions appear warranted: 1. Careful evaluation of the patient's renal functional reserve at the present time. 2. Frequent observation of her arterial tension for a year or more. It may rise gradually. If so, future pregnancies would be of suicidal precariousness. 3. Attention to foci of infection, general health, nutrition, and especially to the hemoglobin content of the blood. Anemia, even of minor degree, is a potent factor in retarding the rehabilitation of injured tissues and especially damaged kidneys. 4. A cold pressor test to determine the patient's arteriolar excitability. Such a test may give valuable prognostic information. 5. Reevaluation of the renal function after twelve to eighteen months. 6. Frequent antepartum observation. If a second pregnancy does occur, this is imperative from the beginning. Should the arterial tension again rise and proteinuria appear, particularly if these occur earlier in the second pregnancy than in the first, therapeutic termination of pregnancy would be justified. After that, further attempts must be urgently discouraged.

TREATMENT OF TAPEWORM

To the Editor:—Will you please give me information regarding any recent, or the best, method and technic in the management of a patient with a tapeworm. I should like to have this information in connection with both the drug and the method of use. A girl aged 5 years, first observed almost a year ago, had been underweight for several months and just prior to that time her mother had noticed several large segments of tapeworm in her stool. She was admitted to the hospital and given routine treatment for tapeworm, the standard amount of oleoresin of aspidium being given for her age. Each time she expelled large sections of the worm—approximately 20 feet with each treatment. The head of the worm was never found in the stool but twice segments of the worm were identified which must have been immediately at the head. The third and last treatment was given about four months ago. As after each of the other treatments she improved for about three months. A few days ago after the administration of a mild purgative she expelled large segments of tapeworm.

J. S. HOLBROOK, M.D., Statesville, N. C.

ANSWER.—Oleoresin of aspidium is the drug of choice for treatment of the beef tapeworm (Taenia saginata) and the pork tapeworm (Taenia solium). The lengths of worm evacuated by the patient after medication and the relative rarity of the pork tapeworm in the United States indicate that one is here dealing with Taenia saginata. For effective treatment the drug must be fresh and must be preceded and followed (or accompanied) by saline purgation.

On the day before treatment the patient should be placed on a semiliquid diet and before retiring should be given one-half ounce (15 Gm.) of sodium sulfate or magnesium sulfate dissolved in a glass of water. Sodium sulfate is preferred because it dissolves mucus away from the head of the worm and thus allows the anthelmintic to act more efficiently. The disagreeable taste of the purgative may be partly disguised by adding to it the juice of half a lemon. On the morning of treatment the patient remains in bed and takes no food. The oleoresin of aspidium is prescribed in three divided doses, to be taken half an hour apart. Each of the three doses should not exceed 20 minims (1.3 cc.) for an adult or 10 minims (0.65 cc.) for a child of 5 years. This medication is followed in one or two hours by saline purgation, similar to that taken the night before treatment. The patient may have food as soon as copious bowel movements have been obtained.

A satisfactory alternative treatment consists in transduodenal intubation of the anthelmintic. The patient is prepared for treatment as indicated. On the morning of treatment the tube is directed into the duodenum under a fluoroscope, after which an emulsion of the following composition (calculated for a child of 5 years), is slowly introduced: oleoresin of aspidium 40 minims (2.6 cc.), mucilage of acacia 20 cc., saturated solution of sodium sulfate 20 cc. No post-treatment purgation is required.

Both of the prescriptions mentioned are usually successful in dislodging and evacuating the heads of tapeworms.

GRANULOCYTOPENIA AND MALARIA

To the Editor:—I should appreciate your assistance in securing some information about the occurrence of agranulocytosis in malaria. I found two references in the German literature. Both refer to cases of malaria which followed malarial therapy for dementia paralytica. Here, however, the picture is slightly obscured by the prior administration of arsenicals and bismuth. Do you know of any reports of agranulocytosis in malaria?

SIDNEY LEIBOWITZ, M.D., New York.

ANSWER.—There are no well authenticated instances of agranulocytosis developing during the course of untreated malaria. Although malaria in some patients may be accompanied by a mild or moderate temporary leukopenia, usually the differential count is unaffected. More often there may be a leukocytosis, especially in the more acute forms of the disease.

It should be pointed out, however, that agranulocytosis has been reported after the administration of certain antimalarial therapeutic agents. Thus quinine has been reported to be causative in several instances (Vitug, W.; Chavez, A., and Austria, G. F.: *J. Philippine Islands M. A.* **15**:464 [Sept.] 1935. Groen, J., and Gelderman, C. J.: *Nederl. tijdschr. v. geneesk.* **78**:3444 [July 28] 1934. Dassen, R., and Fongi, E.: *Rev. Asoc. méd. argent.* **49**:1077 [Aug.] 1935. Corelli, F.: *Hematologica* **15**:663, 1934) while plasmochin apparently produced complete disappearance of granulocytes in one patient (Knighton, J. E., Jr.: *New Orleans M. & S. J.*, p. 755, 1935).

In instances of malarial therapy for dementia paralytica in which arsenical compounds have been administered previously, it would be quite difficult to assume the leukocyte depression to be caused by the malaria, since it is well established that the arsenicals may produce agranulocytosis in occasional instances, Plum having summarized fourteen such cases (Plum, Preben: Clinical and Experimental Investigations in Agranulocytosis, London, H. K. Lewis & Co., 1937, p. 101). Furthermore, in occasional instances the action of the arsenicals on the bone marrow may be delayed and apparently cumulative.

In order to assume the development of agranulocytosis after infection with malaria, it would be necessary to rule out the use of therapeutic agents such as those mentioned, and if such agents have been used in the immediate past prior to development of agranulocytosis the disease most likely would have resulted from them rather than from the malaria.

EPISTAXIS

To the Editor:—Acting as an interpreter at a series of Red Cross first aid lectures, the lecturer spoke on epistaxis. He stated that when one sees bleeding from the right side, the base of the left ring finger should be bound tightly with a string for a while, and vice versa for bleeding from the left side. The next evening an opportunity to prove his statement was presented. The patient was bleeding from the left side. On tying the right ring finger at its proximal portion of the phalanx, I controlled the epistaxis easily and promptly. Can you suggest any basic reason for this? Is there any literature on this subject?

M. PAUL SUZUKI, M.D., Seattle.

ANSWER.—Cases of epistaxis may be conveniently divided into three groups. There is the extremely severe case encountered in surgery of the nose, in malignant growths or as an accompaniment of certain cardiovascular conditions. This group is characterized by a single, profuse hemorrhage. The second class would be cases that are characterized by repeated, moderately severe hemorrhages. These patients frequently have been treated by all the popular home remedies and by at least a half a dozen surgical procedures. Because of a slight ulceration in the nose or of some unusual permeability of the blood vessels, bleeding occurs with every slight trauma. The third group is by far the largest in number of cases. Ordinarily the hemorrhage is slight and is self limited. The popular home remedies for the control of epistaxis of this character are almost as numerous as the procedures treasured by the public for the removal of the common wart. The self-limiting character of this group of cases gives an apparently high incidence of cures to any of the popular methods. There is no known basis of an anatomic or physiologic character that would explain the cessation of the epistaxis as described in the query.

The therapeutic scheme here described seems to be a recrudescence with slight modification of "zone therapy," which had a vogue from about 1915 to 1920. Popular articles appeared in *Everybody's Magazine, Associated Sunday Magazines* and *Every*

Week. In the latter publication, Bruce Barton spoke approvingly of the method. Fitzgerald seems to have been the prominent exponent of this so-called system. In "Zone Therapy or Relieving Pain and Disease" by Drs. William H. Fitzgerald and Edwin F. Bowers (Columbus, Ohio, I. W. Long, 1918) the physician is advised for epistaxis to apply strong constriction to the base of the thumb and index finger of the affected side or in severe cases to apply constriction about all the digits of both hands. Special rubber and metal constricting rings were available in this work. An alphabetical therapeutic index is furnished which tells how to relieve angina pectoris, produce anesthesia, cure asthma, lower blood pressure, raise blood pressure, cure bronchitis, cure brachial neuritis, relieve constipation and so on through the alphabet to writers' cramp and wry neck—all by constricting or pinching the proper fingers and toes. *American Medicine* (November 1921) carried an article by Dr. Fitzgerald on "Zone or Pressure Therapy." In the editorial column it was pointed out that only time would tell the value of this procedure. Time has established its worthlessness.

NURSE AS CARRIER OF AMEBAS

To the Editor:—1. Is it compatible with safety for a nurse having a stool positive for Endamoeba histolytica (cysts) to be on duty in a general hospital? 2. If excluded from duty, how long should the stool and symptoms be free before it is safe for her to return? 3. Are there any other suggestions?

M.D., Oklahoma.

ANSWER.—1. It is safe for a nurse having a stool positive for Endamoeba histolytica to be on duty in the general hospital if she has the knowledge to care for her hands competently so as to prevent any possibility of transfer of the infection to others. This entails keeping the nails well trimmed and careful washing of the hands with soap and water immediately after going to the toilet, as well as at any other time when they may have become contaminated.

2. If the nurse is excluded from duty, she should have three negative stool examinations and be free from symptoms for a week before she is allowed to return. As a rule, however, with the proper care, exclusion of a nurse who is an Endamoeba histolytica carrier from duty is not required.

3. The same regulations should apply to a nurse as to a food handler infested with Endamoeba histolytica.

DETERMINATION OF VITAMIN B_1 BY FLUORESCENCE

To the Editor:—A few weeks ago I saw a clipping to the effect that some one had invented an instrument for the detection and determination of amounts of vitamin B_1 in substances. The principle of the instrument as I recall, was based on the use of the photoelectric cell in some manner. I would greatly appreciate any information concerning such an invention.

M.D., Missouri.

ANSWER.—Presumably the method to which reference is made is that of converting vitamin B_1 (thiamin) into thiochrome by oxidation with alkaline potassium ferricyanide, as originally suggested by Jansen. The resulting thiochrome is extracted from the aqueous solution with isobutanol and quantitatively estimated by the blue fluorescence which its solution exhibits in ultraviolet light. Several other workers have endeavored to perfect the method, so that at the present moment it promises a somewhat higher precision than any other chemical test.

D. J. Hennessy and L. R. Cerecedo published in the January 1939 issue of the *Journal of the American Chemical Society* some modifications of the method tending to adapt it for use in the assay of a variety of biologic fluids and tissues. They also provide for distinguishing free thiamin from its pyrophosphate (cocarboxylase) and give complete references to the earlier literature.

LEUKOPLAKIA IN YOUNG WOMAN

To the Editor:—A woman about 24 years of age has a rather extensive case of leukoplakia. The dentist and I are doing everything possible to correct any possible cause. It seems stationary but is certainly persistent. Is there anything new that can be recommended? The patient appealed to me recently pleading for cure. She is engaged to be married in May.

WARREN T. MCNEIL, M.D., Stockton, Calif.

ANSWER.—In the majority of cases of leukoplakia buccalis no ill effects occur. While leukoplakia is regarded as precancerous, a malignant change need not necessarily follow even after many years. Therefore in most instances no radical treatment need be considered. Of course, the patient's mouth should be inspected at intervals of six months to apprehend any unfavorable changes in the lesions.

There should be an investigation as to the presence of syphilis, which should receive standard treatment if present. Some investigators state that in fully 50 per cent of patients with leukoplakia there is a background of syphilis. Otherwise the patient should not smoke at all. The food should not be highly spiced, very hot or cold. Soothing applications may be made to the lesions, such as tincture of myrrh. Silver nitrate crayons may be used on fissures and erosions, but great care should be taken not to stimulate an already present epithelioma by such superficial caustic applications. Acid mercuric nitrate has been much used, but its action must be strictly confined to the lesions. For local thickenings and irregularities the cautery is best. If a malignant change takes place in any of the lesions, it is treated the same as cancer of the mouth otherwise.

In a patient as young as this woman, leukoplakia is unusual. One should use care to make sure that she does not have lichen planus limited to the mucous membranes, instead of leukoplakia.

TRAUMA AND PAIN UNDER RIBS

To the Editor:—An employee of an oil company fell against a pipe, striking the left lower part of the chest. He complained of intense pain located deep in and under about the ninth and tenth ribs in front. X-ray examination showed that no ribs had been fractured. The pain lasted for about one month but gradually became less intense and finally subsided entirely. There were no abdominal symptoms. Please advise as to the possible causes of this pain. What is the most probable cause? I have been unable to find anything in any books which I have regarding injury of the spleen except rupture. Could a congestion or swelling of the spleen put tension on its capsule and account for such a pain?

C. L. PEARCY, M.D., Salem, W. Va.

ANSWER.—Several possibilities present themselves as explanations of the pain in this case. The contusion of the spleen without actual rupture of the capsule is certainly a strong possibility. It is certainly likely that minor ruptures or tears in the capsule with a small amount of bleeding do occur and heal without anything further being done. Second, rupture of the diaphragm has to be considered; third, a minor injury to the left lobe of the liver with a crack in the capsule and a small amount of bleeding or a localized contusion without bleeding. Fourth, a contusion of the lung on the left side has to be considered; fifth, a contusion involving the heart with effusion of blood in the pericardium with gradual absorption. The fact that the pain has gradually disappeared would seem to indicate that no further treatment is necessary. However, the literature contains many cases of ruptures of the spleen coming on secondarily a month or more after the primary injury has weakened the capsule.

SPINAL FLUID WASSERMANN FAST NOT DESIRABLE TERM

To the Editor:—It is well known that in some cases of syphilis that have had adequate treatment, the blood may be "Wasserman fast." In a case presenting a 4 plus Wassermann (blood) reaction and 4 plus spinal fluid Wassermann reaction and a negative colloidal gold test with no increase in spinal fluid globulin or cell count, is it possible to consider the patient as being "spinal fluid Wassermann fast"? He has had two years of continuous treatment alternating bismuth compounds and neoarsphenamine. Since the spinal fluid was examined six months ago he has received twenty injections (3 Gm.) of tryparsamide and ten malaria chills with no effect on the spinal fluid Wassermann reaction. Clinically he is asymptomatic, and careful systemic and neurologic examinations on several occasions have been completely negative. Can one speak of "spinal fluid Wassermann fast" as well as "blood Wassermann fast"? If so, what is the relative frequency? I would appreciate any information that you can give me.

M.D., New York.

ANSWER.—The use of the term "Wassermann fastness" is deprecated because it implies a clinical state, whereas in reality it is nothing but a group of serologic reports. In practically all patients who have "Wassermann fast" blood tests some explanation can be found for the Wassermann fastness in the fact that the patient either has neurosyphilis or cardiovascular syphilis and only in a few is there no definite explanation to be offered as a result of thorough clinical examination or examination of the spinal fluid. Occasional patients with neurosyphilis are seen in whom the flocculation or complement fixation test on the spinal fluid will remain positive while all other tests on the spinal fluid are negative. This type of report may or may not be of significance as it is frequently seen in patients who, when treatment is stopped, will immediately relapse in the spinal fluid to strongly positive in all factors. On the other hand, it is frequently seen in patients with tabes dorsalis in whom the fixation or complement fixation on the spinal fluid will be positive for years while all other factors on the spinal fluid will remain persistently negative. In the case under discussion, sufficient time has not as yet elapsed to make deductions with regard to the significance of the positive flocculation test on the spinal fluid, as the last spinal fluid test was done only six months ago. As a rule significant changes in the spinal fluid will not be noted for at least two years following the fever course. In the interim it would seem advisable to continue with treatment and in the case under discussion tryparsamide and a bismuth compound or arsphenamine and a bismuth compound

should be given approximately at the rate of two courses a year for the two ensuing years, at least. This implies, of course, that the term "spinal fluid Wassermann fast" should not be adopted because, although experience with spinal fluids is not great enough as yet to attach concrete significance to such a finding, it would appear that several years of observation after intensive treatment has been stopped should be employed before endeavoring to make any deductions as to the significance of this type of spinal fluid.

DERMATITIS FROM CARBON DISULFIDE

To the Editor:—Will you kindly state whether or not it is possible to develop a skin lesion when one has been mildly poisoned by the fumes of carbon disulfide? If this should be possible, what kind of a lesion would develop? I have a patient who says that he became quite ill while handling the chemical and developed patches on the arms and body which were about the size of a silver dollar and are of a brownish color and slightly scaly. Could this chemical produce such a lesion?

H. W. JONES, M.D., Bakersfield, Calif.

ANSWER.—Carbon disulfide (CS_2) usually causes dermatitis at the point of contact. The lesions usually are characterized by erythema, vesicles and degenerative changes in the local peripheral nerves resulting in impaired sensation. Carbon disulfide is a vesicating agent acting chiefly as a fat solvent. Prolonged contact with the skin will cause manifestations characteristic of second and third degree chemical burns. Exposure of the skin to dilute solutions or vapors may cause a drying of the skin as a result of the solvent action on the fats and the cooling effects of evaporation. These lesions may affect whatever parts come in contact with the vapors or fumes. As the lesions heal there may be a residual pigmentation.

Splashes of the chemical on the clothes of the patient may have caused lesions which after healing may have resulted in such patches as those described. If the patches were not the result of healed eczematous lesions, it can be said that they were not caused by carbon disulfide. Pityriasis rosea, fixed drug eruptions such as may be caused by phenolphthalein, patches of parapsoriasis and other similar cutaneous conditions must be considered.

UNDESCENDED TESTIS

To the Editor:—A boy aged 5 years has one testis in the scrotum and the other still in the inguinal canal, though it can be brought down with mild traction. The testis that is in the inguinal canal is considerably smaller than the one that has descended. Would treatment with anterior pituitary-like substance be indicated?

M.D., Illinois.

ANSWER.—The probabilities are that if the testis can be brought down into the scrotum by mild traction it will descend before or at puberty. The whole question involved is therefore whether or not it would be better to have the testis constantly in the scrotum at an earlier period than it would be by "watchful waiting." From experimental evidence it would appear that, the earlier the testes are brought into the scrotum after birth, the more normal they are likely to be. Therefore it would perhaps be best to give this particular boy a short period of treatment using 200 to 300 rat units of gonadotropic substance four times a week for a period of from five to six weeks. If there is any indication of an increase in the size of the external genitalia, the treatment should be discontinued as soon as this is recognized.

HEAT PROSTRATION AND SINUSITIS

To the Editor:—Are there any reports of sinusitis (especially maxillary) following heat prostration? If there are please give me some information on the cases and if possible some literature to read on the subject.

E. H. COACHMAN, M.D., Muskogee, Okla.

ANSWER.—A search of the literature for the past ten years and standard textbooks on rhinology fails to reveal any information on sinusitis following heat prostration.

ANTITYPHOID VACCINE

To the Editor:—Some time ago I noticed that the army had discontinued using paratyphoid A and B for vaccine, using simply Bacillus typhosus. Is this a generally accepted plan? I note that the majority of the biologic companies are still using the old formula which contains paratyphoid A and B.

W. S. CRAWFORD, M.D., Tulsa, Okla.

ANSWER.—The antityphoid vaccine now used by the army is being used more and more widely, but vaccine made according to the old formula is used also. All antityphoid vaccines on the market are tested for antigenic values and are approved by the U. S. Public Health Service.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. Sec. Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: *Cincinnati, Nov. 15.* Appointments must be made before July 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF UROLOGY: White Sulphur Springs, W. Va., May 26-28. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Alabama January Examination

Dr. J. N. Baker, secretary, Alabama State Board of Medical Examiners, reports the written examination held at *Montgomery*, Jan. 3-5, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. One candidate was examined and passed. The following school was represented:

School	PASSED	Year Grad.	Per Cent
Tulane University of Louisiana School of Medicine		(1938)	85.2

Nevada Reciprocity and Endorsement Report

Dr. John E. Worden, secretary, Nevada State Board of Medical Examiners, reports three physicians licensed by reciprocity and one physician licensed by endorsement after an oral examination held at Carson City, Feb. 6, 1939. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of California Medical School		(1927)	California
State University of Iowa College of Medicine		(1926)	Minnesota
Jefferson Medical College of Philadelphia		(1920)	California

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Stanford University School of Medicine		(1938)	N. B. M. Ex.

Hawaii January Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, Territory of Hawaii, reports the oral and written examination held at Honolulu, Jan. 9-12, 1939. The examination covered ten subjects and included eighty questions. An average of 75 per cent was required to pass. Four candidates were examined, three of whom passed and one failed. Four physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of California Medical School		(1934)	83.1
University of Colorado School of Medicine		(1931)	82.4
Washington University School of Medicine		(1937)	80.8

School	FAILED	Year Grad.	Per Cent
Nippon Ika Daigaku, Tokyo		(1937)	59

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Yale University School of Medicine		(1931),	(1935) N. B. M. Ex.
Northwestern University Medical School		(1937)	N. B. M. Ex.
Johns Hopkins University School of Medicine		(1935)	N. B. M. Ex.

Book Notices

Scarlet Fever. By George F. Dick, M.D., D.Sc., Professor of Medicine, University of Chicago, and Gladys Henry Dick, M.D., D.Sc. Cloth. Price, $2. Pp. 149, with 8 plates. Chicago, Illinois: Year Book Publishers, Inc., 1938.

Containing a concise account of the application of the investigations of the authors to the prevention and treatment of scarlet fever, this book summarizes their articles on these matters during the past twenty years or more. The demonstration by human experiments on the part of the authors that scarlet fever may be caused by hemolytic streptococci was followed by the discovery of a specific streptococcic scarlet fever toxin, which in turn led to the Dick test for susceptibility to scarlet fever, to successful active immunization against scarlet fever and to the use in treatment of a specific antitoxin. The book describes the practical use of these measures and the results obtainable. The preparation of the scarlet fever toxin and the technic of testing its potency are described in detail. The book is a landmark in the history of scarlet fever.

Pyrétothérapie. Par Charles Richet, professeur agrégé à la Faculté de médecine de Paris, Jean Surmont, médecin électro-radiologiste des hôpitaux de Paris, et Pierre Le Gô, électro-radiologiste des Asiles de la Seine. Paper. Price, 50 francs. Pp. 195, with 28 illustrations. Paris: Masson & Cie, 1938.

This is the first monograph on pyretotherapy, or artificial fever, to appear in French. The authors divide their thesis into five main chapters entitled biologic principles, technic, clinical results, pathogenesis of pyretotherapy and conclusions. They conclude that there is a direct relationship between body temperature and inhibition of the growth of certain microorganisms, especially the gonococcus and Spirochaeta pallida. This bactericidal action of heat can be demonstrated in vitro and in vivo, though it is more pronounced in vivo. They state that this may be due to the well known acceleration of most chemical reactions under the stimulating influence of heat. They further conclude that the source of the fever makes little difference, that the micro-organisms are destroyed in vivo at temperatures compatible with life and that fever modifies human physiologic reactions to a profound degree.

The second and longest chapter of the book discusses the production of fever. Inoculation with malaria and the production of relapsing fever and of sodoku, or rat bite fever, are described, with their advantages and disadvantages. In the section on the use of suspensions of killed micro-organisms, the action of dmelcos vaccine, consisting of an emulsion of the Ducrey bacillus, which is more widely used in France than in the United States, is described in detail. The authors conclude that this vaccine presents the advantages of a quick rise of the febrile curve and the possibility of predetermining the amount of fever, since the dose is proportional to the amount of the vaccine injected. They are less pleased with typhoid, gonococcus, paracoli and yeast emulsions as well as bacterial proteins, such as tuberculin. Chemicals for producing fever are also mentioned, such as milk, sodium nucleinate, nucleoprotein, turpentine and benzine. The authors conclude that colloidal solutions of silver and suspensions of sulfur in oil are the only chemicals that are really practical. The rest of the chapter is devoted to a thorough discussion of the physical methods of elevating the temperature. An error is the statement that it is difficult to raise the temperature of the human body above 40 C. (104 F.) by means of damped diathermy waves. The discussion on external heating contains a brief description of the various wavelengths and their frequency, clarified by a useful chart. The section dealing with the machines used for producing short radio waves is comprehensive and clear. Naturally French machines occupy the foreground, but this is to be expected in a book intended for French physicians. A new pyrometer constructed by Le Gô seems to be better than the instruments in common use in the United States. Accidents such as burns, heat stroke and involvement of the cardiovascular system are dealt with in detail. The authors distinguish between the effect of active and of passive pyretotherapy. The former is produced by the body itself as a result of inoculations or injections and the latter by transferring energy into the body. They liken active pyretotherapy to shock. Finally the contraindications of treatment are ably discussed in detail.

The third chapter, dealing with the clinical results of pyretotherapy, is clear and comprehensive and illustrated with frequent case reports. The results achieved in the treatment of gonorrhea and all its complications, primary and secondary syphilis, syphilitic optic atrophy, tabes, cerebrospinal syphilis and dementia paralytica are discussed in detail. The authors then describe the treatment of chorea minor, encephalitis, Parkinson's syndrome, multiple sclerosis, poliomyelitis, psychoses and other psychiatric conditions, cardiovascular diseases, gout, arthritis, articular rheumatism, neuritis, asthma, soft chancre, diseases of the ears, nose and throat, staphylococcic infections, tuberculosis, ocular diseases, renal diseases, undulant fever, meningococcic meningitis, diseases of the lungs, dermatoses, obesity, carcinoma and mycosis fungoides. It is a great credit to the book that this widely divergent material dealing with therapeutic results is carefully analyzed and classified. The point of view is always conservative and no overstatement is made. Whenever the clinical results are doubtful or valueless the authors state this fact frankly and openly.

The two short final chapters contain the authors' theories on the reasons for the benign action of fever, either active or passive, on diseases as well as their own conclusions about the application of this therapy. Finally there is a bibliography of less than 150 references, which is not nearly complete, since the world literature on artificial fever alone now comprises more than 500 contributions. There is no index.

In spite of the minor defects mentioned the book is an excellent contribution to pyretotherapy. It fills a real need as a volume for reference, from which the physician can learn the technic of fever production as practiced in the United States and abroad.

Textbook of Neuro-Anatomy and the Sense Organs. By O. Larsell, Ph.D., Professor of Anatomy, University of Oregon Medical School, Portland. Cloth. Price, $6. Pp. 343, with 232 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1939.

Olof Larsell has presented a well organized, orthodox discussion of the structure, both gross and microscopic, of the central, peripheral somatic and sympathetic nervous systems. Sufficient physiologic and clinical data have been appended to enhance the student's interest in the subject and to indicate the more important correlations between structure and function. Although the "book has been written primarily for the first year medical student" and is accordingly not encyclopedic, it will prove of value and interest to many more advanced students. This is particularly true of the chapter dealing with the cerebellum and pons, a subject to which the author has been a noteworthy contributor. The discussion of the various end organs, cutaneous, tendinous and muscular, as well as the organs subserving specialized sensations, such as the taste buds, the olfactory epithelium, the retina, the vestibular apparatus and the cochlea, is a valuable addition to the discussion of the nervous system.

Unfortunately the text is neither always clear nor easily read; there are not a few errors which it is hoped will be corrected in future editions. On page 259 in the second paragraph from the bottom the statement of fact is literally correct but the meaning implied is false. One would conclude that, whereas Poljak and Brouwer found no optic fibers from the pulvinar to the calcarine cortex, Walker and Le Gros Clark did. This is not correct. The fibers found by Walker and Le Gros Clark were not to the calcarine cortex (area 17) but to other parts of the occipital lobe and were not regarded as optic fibers. The statement on page 97 that "special visceral efferent fibers arise from the motor VII nucleus and pass through the motor branches of the VII nerve to the mimetic muscles, derived from the musculature of the hyoid arch" is hardly designed to inform first year medical students that the seventh cranial nerve innervates the muscles of the face. The discussions, principally on pages 76 to 81, relative to the pathways subserving the sensations of touch and of pain are confused and even contradictory. On page 78 one finds the implication that the ventral spinothalamic tract alone carries the sensations of touch and pressure in the statement that destruction of that pathway abolishes the perception of such stimuli. There are other pathways for touch and pressure sensibilities in the posterior and lateral columns accord-

ing to page 80 and in the posterior and ventral columns according to page 90, and the further contradictory statement that the posterior columns have to do only with joint and position sense and with two point discrimination appears on page 79. On page 80 is found the erroneous statement that the destruction of the anterior white commissure of the spinal cord results "in loss of pain and temperature sensation on the opposite side of the body below the level of the lesion." The omission of the important spinothalamic tract from figures 90, 92 and 94, as well as others, is noteworthy. In the discussion of the afferent components of the glossopharyngeal nerve (page 95) all mention of the fibers of the carotid sinus nerve and of the tympanic nerve has been omitted, and the statement that the general somatic afferent fibers of this nerve are "distributed to the skin of the back of the ear and mastoid region" is at least open to question. In the legend to figure 19 the letters b and l have surely been interchanged. The statement on page 81 that the spinotectal tract is "apparently a correlation pathway" is meaningless and needs clarification. In spite of evidence (Stern) that the rubrospinal tract is little more than vestigial in man, this tract is illustrated and discussed as though it occupied a position of size and importance in man comparable to that in lower mammals.

The numerous illustrations, which are both original and selected from the literature, are well chosen and beautifully reproduced. The salient features of the descending and ascending tracts of the spinal cord are listed in table I and the principal visceral efferent or autonomic pathways in table II, which will prove most useful to the prospective student. The type has been well chosen. There is a brief bibliography appended to each chapter and a satisfactory index.

Experimentelle Untersuchungen über Farbengleichungen im zentralen und parazentralen Sehen. Von G. F. Olsson. Inauguraldissertation. Medizinische Fakultät zu Uppsala. Paper. Pp. 153, with 11 illustrations. Upsala, 1938.

This study of color equations was submitted as an inaugural dissertation. Because of its highly technical nature and limited scope it takes on the aspect of a thesis which in America might be submitted for a degree of doctor of philosophy. There is a frank and complete discussion, introductory to the problem, concerning previous investigations in this and kindred fields. The present work was accomplished with the aid of Gullstrand's color mixing apparatus, and the author used his own practically emmetropic eyes for all his investigations. He reaffirmed that the curves for complementary colors for central and paracentral vision diverge from one another and cross in the blue-yellow sector. In a consideration of color equations and their influence by the yellow macular substance Olsson concludes that, as far as the study of central and paracentral vision is concerned, such a theory is untenable. The pamphlet includes a picture and interpolation table for the Gullstrand color mixing apparatus, protocols of the experiments and a fairly complete bibliography.

Midwifery. By Ten Teachers. Under the direction of Clifford White, M.D., B.S., F.R.C.P. Edited by Sir Comyns Berkeley, Clifford White and Frank Cook. Sixth edition. Cloth. Price, $6. Pp. 676, with 262 illustrations. Baltimore: William Wood & Company, 1938.

In the preparation of this edition the aid of a number of new obstetricians was enlisted to replace the teachers who resigned. Some new material has been added and many of the old illustrations have been replaced with more instructive ones. In the discussion of the toxemias of pregnancy there is a peculiar division under the headings vomiting of pregnancy, the toxemias of pregnancy, albuminuria of pregnancy, preeclampsia and eclampsia, and icterus gravis gravidarum and toxic hyperemesis. The subject of chronic nephritis is included in the chapter on albuminuria. In the treatment of septic abortion the authors advocate removal of the contents of the uterus by means of the finger. However, this procedure may be just as dangerous as the use of a curet, against which the authors warn. In the discussion of pelves there is no mention of the recent important contributions made by Thoms and by Caldwell, Moloy and D'Esopo. The authors believe that paraldehyde is probably the best analgesic and that chloroform is the anesthetic of choice during labor. Mention is omitted of local infiltration anesthesia, although a paragraph is devoted to spinal anesthesia in spite of the fact that this form of anesthesia is particularly dangerous for pregnant women. This is the first edition in which illustrations of the low cervical cesarean section appear. The book is well written and in a uniform style notwithstanding that ten men collaborated in its preparation. The great wealth of material should permit it to retain its leadership among English textbooks on obstetrics.

Atlas de phonocardiographie clinique. Par A. Calô, assistant étranger à la Faculté de médecine de Paris. Préface du Professeur A. Clerc. Paper. Price, 60 francs. Pp. 104, with 150 illustrations. Paris: Masson & Cie, 1938.

Modern medicine is in search of precision instruments capable not only of rendering dependable service in the routine examination but also of opening new avenues of approach to unexplored regions of physiology and pathology. The importance of the analysis of heart sounds in the diagnosis of various cardiopathies induced Einthoven, Weiss, Wiggers and many others to construct ingenious sound recording apparatus, which however remained confined to a few laboratories on account of their imperfections, cost, bulk and fragility. Only in recent years, especially since the advent of radio, has the progress in this field been great, and heart sound recording devices can now be used not only for the study of the genesis and mechanism of normal sounds but also for the diagnosis of murmurs and pathologic rhythms. After a brief description of the apparatus the author devotes some space to a discussion of the graphic characteristics of normal and pathologic sounds, offers their classification, points out the advantages and limitations of the method and submits reproductions of thirty-seven phonocardiograms. In each instance the sound record is accompanied by an electrocardiogram, sphygmogram and orthodiagram, thus facilitating the interpretation of the observations. It is interesting that the phonocardiogram is able to detect certain acoustic phenomena not perceptible with the unaided ear, e. g., auricular murmurs in the course of an auriculoventricular dissociation and certain incipient forms of the gallop rhythm.

Bacteriology for Medical Students and Practitioners. By A. D. Gardner, D.M., F.R.C.S., Professor in Bacteriology, University of Oxford, Oxford. Second edition. Cloth. Price, $2.25. Pp. 274, with 32 illustrations. New York & London: Oxford University Press, 1938.

This pocket size book is well written and is in accordance with current thought in the field of bacteriology. A systematic and rational nomenclature has been followed which arranges the various kinds of bacteria in as many broad groups of genera as there are clear and constant group differences. In place of the indefinite names, such as Bacillus welchii and Bacillus melitensis, the author uses Clostridium welchii, Brucella melitensis, Pasteurella pestis and so on, names which differentiate and place each of the species in a definite group. Numerous tables separate species of like organisms. Particular attention is given to the practical interpretation of laboratory tests. The author feels that a knowledge of the contents of his book, supplemented by practical work and lectures, will sufficiently equip a student for the bacteriologic aspect of medical practice, although wider reading is advocated, especially on parts of the subject the student finds most interesting. This practical little book can be heartily recommended for the physician and as a help to the medical student in his course in bacteriology.

The Physiology of Anesthesia. By Henry K. Beecher, A.B., A.M., M.D., Instructor in Anesthesia, the Harvard Medical School, Boston. Cloth. Price, $3.75. Pp. 388. New York, Toronto & London: Oxford University Press, 1938.

At last a physiologist has reviewed the literature concerning the physiology of anesthesia and has presented a splendid bibliography, arranging the available data on the basis of both general and local anesthesia and also according to the various systems such as the respiratory and circulatory systems and according to the effect of anesthetic agents on each of the vital organs. It was the author's hope that this book might be used in medical teaching and reference work and more particularly that it should stimulate research. It should do each of these things and without doubt will speed the already rapid development of the specialty of anesthesia.

Refraction of the Human Eye and Methods of Estimating the Refraction Including a Section on the Fitting of Spectacles and Eye-Glasses. By James Thorington, A.M., M.D., F.A.C.S. Revised and edited by J. Monroe Thorington, B.S., A.M., M.D., Associate Ophthalmologist, Presbyterian Hospital, Philadelphia. Third edition. Cloth. Price, $3.50. Pp. 412, with 283 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

The third edition of this useful little volume, in which a new format appears, extends Thorington's contributions to the subject over a period of forty years. As in the previous editions, important contributions are the simplicity and lucidness with which the subject is treated and the freedom from advanced mathematical formulas, which only confuse the beginner. Sections on the muscular insufficiencies and orthoptic training have been added, and, while these are not extensive, they give the important facts. A few typographical errors occur, such as the spelling of color on page 31 and the notation on page 118 that vision of the 60 line at 6 meters is recorded 4/60. This edition is accepted as one of the notable works in the introduction to refraction of the eye.

Die Gesetze des normalen Träumens. Von Dozent K. Leonhard, Oberharzt der Nervenklinik Frankfurt a. M. Boards. Price, 5.40 marks. Pp. 124. Leipzig: Georg Thieme, 1939.

In the author's introduction he states that the literature concerning dreams contains little except psychoanalytic concepts with their fantastic dream symbols, and that in Germany they now know that it was the racially foreign psyche that was responsible for the one-sided relating of dreams and sexuality. After this characteristic beginning he proceeds to describe dreams and states of sleep in a most superficial manner, completely ignoring the literature. He gives no clue to any scientific knowledge. The wishful basis of dreams he refutes with the ancient, many times considered, argument that anxiety dreams cannot express a wish. The author proudly concludes that the dream mirrors the varying need for rest of the nervous system; the contents have no significance. The book is not worth reading.

Vital Energetics: A Study in Comparative Basal Metabolism. By Francis G. Benedict, Director, Nutrition Laboratory, Carnegie Institution. Carnegie Institution of Washington Publication No. 503. Paper. Pp. 215, with 46 illustrations. Washington, D. C.: Carnegie Institution of Washington, 1938.

This is a comparative survey embracing basal metabolism measurements of all adult animal species studied at the Nutrition Laboratory. Considerable space is devoted to a painstaking consideration of the conditions necessary for comparative measurements of heat production, both intraspecific and interspecific, with analyses of the difficulties involved and the criteria employed. Data are presented for the various warm-blooded species on the basis of twenty-four hour heat production with reference to body weight. Then interspecific comparisons are made, expressed in terms of total heat production per kilogram of body weight and per square meter of surface area. The accompanying charts are plotted arithmetically. The warm-blooded animals considered range from the 8 Gm. mouse to the 4,000 Kg. elephant. Comparisons are made also between warm-blooded and cold-blooded animals at low cell temperatures and at 37 C. It is notable that among animals of different species but in the same weight group great differences in total heat production, as well as in metabolism expressed per kilogram and per square meter, obtain; for these discrepancies there is as yet no answer. Much emphasis is placed on the questionable validity of the surface area concept and considerable evidence is presented to indicate (p. 121) "how futile is the attempt to ascribe a constant value to the heat production of different animal species expressed per unit of surface area." Moreover, throughout the discussion the necessity is stressed of recognizing heat production rather than heat loss as the fundamental biologic activity involved in metabolic measurements. Finally, the factors which may be involved in the metabolic differences in and between species are considered and, in essence, best future progress is predicated on attempts to correlate differences in metabolic intensity with differences in bodily configuration and with differences in the composition, chemistry and distribution of the blood. A "unifying principle," if there is one which would serve as a common denominator for all animal species, is as yet an elusive quantity, and the key to the wide differences in the level and intensity of "vital energetics" is still not at hand. Indeed, one prime purpose of this monograph is to turn attention from the simple concept of heat loss as a unifying principle—which the author regards as fallacious—to the more subtle and profound differences between individuals and species, in which ultimately such a unifying principle may be discovered.

You Can Sleep Well: The A B C's of Restful Sleep for the Average Person. By Edmund Jacobson, M.D. Cloth. Price, $2. Pp. 269, with 40 illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1938.

The theory of sleep induced by relaxation is expounded by the author through the conversations of a mythical doctor and patient. The book is intended for laymen, although it is ironically stated in the preface that scientists and physicians may learn from it also. It is exceedingly difficult to review a work for popular consumption, especially one as breezily written as this, which skips lightly over controversial matters, conflicting evidence and other theories and which dogmatizes the author's own views. The lay reader is compelled to follow Jacobson's implied attitude of take it or leave it.

Del carcinoma primitivo broncopulmonar. Por Niceto S. Lôizaga, docente libre de Clinica de enfermedades infecciosas de la Facultad de ciencias médicas de Buenos Aires. Paper. Pp. 221, with illustrations. Buenos Aires: Librería y Editorial "El Ateneo," 1938.

This monograph is based on an extensive review of the literature and on a study of forty-six cases observed at the Hospital Muniz during the last ten years. The full histories are given of twenty-one patients studied completely in all respects, clinically as well as anatomically. The structure of primary cancer of the lung is well illustrated by photographs. The bibliography covers some twenty pages. The book is a significant addition to the growing literature on cancer of the lung.

The Scientist in Action: A Scientific Study of His Methods. By William H. George, M.Sc., Ph.D., F.Inst.P., Honorary Lecturer in Physics, University of Sheffield, Sheffield, England. Cloth. Price, $3. Pp. 354, with 31 illustrations. New York: Emerson Books, Inc., 1938.

The choice of both British and American scientific clubs, this book deals with scientific research as a form of human action. The producers as well as the products of scientific research are examined and described. "The scientist himself becomes a part, not only of his apparatus, but of his results also. To talk about science without talking about the scientist is rapidly becoming meaningless. The research worker, as a pure-reason machine, is abandoned for the idea of a biological unit reaching to, and acting upon, an everchanging environment." The first part, on the scientific outlook, discusses qualities of scientific research (action, facts, the arrangement of facts, newness), description versus absolute truth, change and the uniformity of nature, the should-ought mechanism and assessment of value; the second part, getting scientific facts, the eyewitness's observation, scientific observation, pattern, the question whether facts are first seen in isolation, selection and abstraction; the third part, arranging scientific facts in chapters on order, laws and classification, pattern in action, the scientific theory, problems of theorizing, some factors in experimental technic and the future of experimental research. The fourth part, or conclusion, contains a personal explanation because of the stress laid on the "biologic factors" in research and a summary of the trends and conclusions of the discussion. The book is of extreme interest to those who are concerned with the methods and meaning of science. In a vigorous style it gives a clarifying and stimulating treatment of the scientist in action in research.

Biology for Pharmaceutical Students and Others. By S. Mangham, M.A., Professor of Botany, University College, Southampton, England, and A. R. Hockley, B.Sc., Lecturer in Zoology, University College, Southampton. Cloth. Price, $6.50. Pp. 613, with 299 illustrations. Baltimore: William Wood & Company, 1938.

Written primarily for students of pharmacy, this book is well suited to any one desiring a succinct account of the basic structural features and functions of plants and animals. It deals also with development, endocrine organs, vitamins, mendelism, heredity and evolution. The structure of flowering plants is fully presented. The book is amply illustrated with adequately

labeled diagrammatic figures, largely original and very well done. In its completeness, wide scope and abundance of illustrations this textbook of biology (in the sense of a combination of botany and zoology) is of unusual excellence.

Comparative Anatomy and Physio-Pathology of the Autonomic Hypothalmic Centres. By Dr A. A Boon. Acta Psychiatrica et Neurologica Supplementum XVIII. Paper Pp 129, with 22 Illustrations Copenhagen. Einar Munksgaard, Haarlem De Erven F. Bohn, 1938.

In this volume the author summarizes the literature on his topic and confirms certain anatomic observations already well established. The book is of some value for quick reference to the literature but adds nothing of significance.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Compensability of Recurrence of Hernia Following Operative Repair.—In May 1932, the claimant sustained a "double hernia," which apparently was successfully corrected by an operation. He began his employment with the defendant company in August 1933. On May 21, 1934, as the result of strain in lifting a large piece of coal in the course of his employment in one of the defendant's mines, he sustained a bilateral inguinal hernia and a right femoral hernia. On June 11 an operation for the correction of these hernias was performed by a physician employed by the defendant company. The incisions "healed firmly" without any infection. On July 2, the claimant was discharged from the hospital where the operation had been performed and reported that he was able to return to work on August 6. In accordance with an agreement for compensation, the claimant was paid compensation up to August 6.

Subsequently, while outside of his employment, he felt a little pain following a forceful sneeze and thereafter another left inguinal hernia developed The claimant then applied to the workmen's compensation board for reinstatement of the agreement for compensation on the ground that his disability had recurred. It was conceded that the sneeze was the immediate cause of the hernia. However, the claimant contended that he had sustained a recurrence of his hernia due to a weakened condition of his left abdominal wall following the operation. The defendant, on the other hand, contended that the claimant had fully recovered from the operation, that his abdominal wall had not been left in a weakened condition and that the claimant had not sustained a recurrence of his hernia but had sustained a new injury due to the sneeze which occurred outside of his employment, for which injury the defendant was in no way responsible. The board found that the claimant had "sustained a recurrence of the hernia on account of a physical weakness as a result of his previous hernial operation and due to the sneeze," fixed August 16 as the date of its recurrence and reinstated the compensation agreement. From a judgment of the court of common pleas, Allegheny County, affirming the award of the board, the employer appealed to the superior court of Pennsylvania.

The burden, said the superior court, rested on the claimant to prove that his hernia most probably would not have developed if his abdominal wall had not been in a weakened condition as a result of the operation. To support his claim for compensation, the claimant relied on the testimony of a physician who examined him following the alleged recurrence. This medical witness testified that based on his examination he was of the opinion that the claimant had sustained a recurrence of his hernia. After a herniotomy, he testified, there is a period of from eight to fourteen weeks, depending on the individual case, during which there is a definite weakness in the abdominal wall, which weakness is not a fault of the operative work but is due to the fact that the tissues are still "knitting." During this period a cough, sneeze or a lifting might produce a recurrence of a hernia. He frankly admitted that he could not state definitely whether the "healing process" had been completed in this case or whether the hernia was a new injury due to the sneeze or was attributable to a weakened condition of the abdominal wall. On the other hand, the company physician testified that a sneeze or anything that would increase the intra-abdominal pressure might produce a hernia even in an individual who had never had a herna and that in his opinion the claimant did not have a weakened condition of his abdominal wall as a result of the operation and that the sneeze was a productive factor in the causation of the herna

Although, said the court, the testimony on behalf of the claimant was not as positive as might be desired, it could not be said that the finding of the board was unsupported by competent evidence. Furthermore, the board was at liberty in arriving at its conclusion, to take into consideration the entire course of events following the claimant's discharge from the hospital. In the judgment of the court there was justification for reinstating the agreement for compensation How ever, the court was of the opinion that the date of recurrence as fixed by the board, Aug. 16, 1934, was not supported by the evidence. The evidence merely showed that the herna was not in existence on Sept. 27, 1934, but that it had developed prior to Dec. 1, 1934. The court concluded that there was no justification for reinstating the agreement as of any date prior to Sept. 27, 1934.

Accordingly, the court ordered that the judgment be modified and as modified affirmed.—*Roberts v. Hillman Coal & Coke Co. (Pa.), 200 A. 128.*

[illegible] Association, Montebello, Canada, May 31-June 1 University of Pennsylvania Medical Laboratory.

American Gynecological Society, White Sulphur Springs, W. Va, May 22-24 Dr. Richard W. TeLinde, 11 East Chase St, Baltimore Secretary.

American Laryngological Association, Rye, N. Y., May 24-26 Dr James A Babbitt, 1912 Spruce St, Philadelphia, Secretary.

American Neurological Association, Atlantic City, N. J, June 5-7 Dr Henry A. Riley, 117 East 72d St, New York, Secretary.

American Ophthalmological Society, Hot Springs, Va, June 5-7 Dr Eugene M. Blake, 303 Whitney Ave, New Haven, Conn, Secretary

American Orthopedic Association, Buffalo, N. Y., June 5-8 Dr Ralph K. Ghormley, 110 Second Ave. S W., Rochester, Minn, Secretary

American Otological Society, New York, May 22-23 Dr. Thomas J Harris, 104 East 40th St, New York, Secretary.

American Proctologic Society, Brooklyn, N. Y., June 25-27. Dr Curtice Rosser, 710 Medical Arts Bldg, Dallas, Texas, Secretary

American Urological Association, White Sulphur Springs, W Va, May 29-June 1. Dr. Clyde L. Deming, 789 Howard Ave, New Haven Conn., Secretary.

Connecticut State Medical Society, New Haven, May 25-26 Dr Creighton Barker, 258 Church St, New Haven, Secretary

Maine Medical [illegible] Springs, June 25-27. Dr F R. Carter, 22 Ars [illegible] ary.

Massachusetts M [illegible] June 6-8. Dr. Alexander S Begg, 8 Fenway, Boston, Secretary.

Medical Library Association, Newark, N. J., June 27-29. Miss Janet Doe, 2 East 103d St, New York, Secretary.

Minnesota State Medical Association, Minneapolis, May 31-June 2 Dr B. B. Souster, 11 West Summit Ave, St Paul, Secretary.

Montana, Medical Association of, Butte, June 28-30. Dr. Thomas L. Hawkins, 50 North Main St., Helena, Secretary.

National Gastroenterological Association, New York, June 1-2 Dr G. Randolph Manning, 1819 Broadway, New York, Secretary.

National Tuberculosis Association, Boston, June 26-29. Dr. Charles J Hatfield, 50 West 50th Street, New York, Secretary.

New Hampshire Medical Society, Manchester, June 8-9. Dr Carleton B Metcalf, 5 South State St., Concord, Secretary.

New Jersey, Medical Society of, Atlantic City, June 6-8. Dr. Alfred Stahl, 55 Lincoln Park, Newark, Secretary.

Pacific Coast Oto Ophthalmological Society, San Francisco, June 19-22. Dr. C. Allen Dickey, 450 Sutter St, San Francisco, Secretary

Pacific Northwest Medical Association, Spokane, Wash, June 26-29 Dr C. W. Countryman, 407 Riverside Avenue, Spokane, Wash, Secretary

Rhode Island Medical Society, Providence, June 7-8 Dr. Guy W. Wells 124 Waterman St., Providence, Secretary

Society of Surgeons of New Jersey, Elizabeth, May 25. Dr. Walter B. Mount, 21 Plymouth St, Montclair, Secretary.

Vancouver Medical Association Summer School, Vancouver, B C, June 6-9. Dr. W. W. Simpson, 203 Medical Dental Bldg, Vancouver, B C. Secretary.

West Virginia State Medical Association, White Sulphur Springs, July 10-12. Mr. Joe W. Savage, Public Library Bldg, Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Am. J. Syphilis, Gonorrhea and Ven. Dis., St. Louis

23: 143-276 (March) 1939

Choice of Bismuth Preparation. Clinical Resume of Excretion and Retention Studies. H. N. Cole, T. Sollmann and Katharine Henderson, in collaboration with G. W. Binkley, H. Connors, G. Cooper, W. R. Lover, H. Reichle, W. F. Schwartz, D. Seecof and M. Sullivan, Cleveland.—p. 143.

*Treponemicidal Activity of Arsphenamine and Neoarsphenamine in Vitro, with Special Reference to Citrated Blood and Suggested Method for Prevention of Transfusion Syphilis. Clara C. Kast, C. W. Peterson and J. A. Kolmer, Philadelphia.—p. 150.

*Acquired Syphilis in Children. Epidemiologic and Clinical Study. F. R. Smith Jr., Baltimore.—p. 165.

Id. Case Reports on Four Sisters. A. G. Schoch and W. E. Long, Dallas, Texas.—p. 186.

Acetarsone Orally in Treatment of Acquired Syphilis in Adults. H. M. Robinson and H. M. Robinson Jr., Baltimore.—p. 188.

Treatment of Acute Anterior Urethritis with Silver Picrate. F. Knight and H. A. Shelanski, Philadelphia.—p. 201.

Gonococcic Endocarditis. Report of Case with Autopsy. W. M. Brunet, Chicago.—p. 207.

Sobisminol (Sodium Bismuthate Soluble) in Treatment of Experimental Rabbit Syphilis. C. Shaw, J. E. Kemp and Elsie Mae Fitzgerald, Chicago.—p. 210.

Acquired Syphilitic Interstitial Keratitis. Report of Two Cases. H. Pariser, Philadelphia.—p. 214.

Observations on Incidence of Latent Paroxysmal Hemoglobinuria as Evidenced by the Donath-Landsteiner Phenomenon. L. V. Dill, with technical assistance of Ida Douvros and C. E. Isenhour, Durham, N. C.—p. 220.

Erythema of the Ninth Day Syndrome Associated with Bismuth Therapy. L. Goldman and G. E. Clarke, Cincinnati.—p. 224.

Acute Fatal Liver Necrosis Following Tryparsamide Administration: Report of Two Cases. H. L. Traenkle and F. A. Dolce, Buffalo.—p. 228.

Gumma of the Brain. B. J. Alpers, Philadelphia.—p. 233.

Spirocheticidal Activity of Arsphenamine.—Because of the high spirocheticidal activity of arsphenamine (disodium) and neoarsphenamine, Kast and her co-workers advise that as a means for the prevention of transfusion syphilis either compound be added to citrated human blood in a final dilution of 1:10,000 whenever syphilis of the donor is suspected or known to be present. Ill or toxic effects have not been observed in eight patients.

Acquired Syphilis in Children.—Smith describes some of the clinical and epidemiologic features of acquired syphilis in 125 children 10 years of age or less. They are authenticated cases that the author collected from the larger pediatric clinics of the eastern and southern United States. In the Johns Hopkins Hospital only forty-five cases of early acquired syphilis in children less than 11 years of age were observed in seventeen years (1920-1937), during which time there were ninety cases among children from 11 to 15 years of age and 4,487 cases among adults. The disease was acquired through attempted sexual intercourse by forty-three, through kissing by fifteen, through a household contact by fourteen and through blood transfusion by nine, on forty-four acquisitions there are no data. There were approximately twice the number of females affected as males. This difference became more marked with advancing age. In most instances of infection by illicit sexual intercourse a female child was infected by an adult male. Also the risk of infection from casual household contact seems to be greater for female than for male children. Most of the patients were from families belonging to the lower economic groups whose hygienic habits were poor and in whose homes overcrowding was prevalent. The clinical characteristics of acquired syphilis in children do not differ materially from those of acquired syphilis in adults. Treatment produced satisfactory clinical and serologic results. The risk of acquiring syphilis by the ordinary contacts between individuals living or working in the same house seems to be small, but when the contact is intimate as in the case of young children with their mother or nurse the risk is sufficient to have a practical significance. Infection by playmate contact is usually acquired by secretive infantile sex practices rather than by the ordinary relationships of play. The nine cases of transfusion syphilis emphasize the necessity for careful pretransfusion examination of all donors, including parents and relatives.

Annals of Internal Medicine, Lancaster, Pa.

12: 1175-1402 (Feb.) 1939

Prophylaxis in Allergy. R. A. Kern, Philadelphia.—p. 1175.

*Chronic Brucellosis (Undulant Fever): Analytic Study of the Positive Reactors Among School Children. T. E. Angle and W. H. Algie, Kansas City, Kan.—p. 1189.

Variation of Blood Pressure with Skeletal Muscle Tension and Relaxation. E. Jacobson, Chicago.—p. 1194.

Human Autonomic Pharmacology. XV. Effect of Acetyl Beta-Methylcholine Chloride (Mecholyl) by Iontophoresis on Arterial Hypertension. J. Loman, M. T. Lesses and A. Myerson, Mattapan, Mass.—p. 1213.

Low Chest and Upper Abdominal Pain. W. M. Ballinger, Washington, D. C.—p. 1223.

Chemical Nature of Heart Failure. G. Herrmann and G. M. Decherd Jr., Galveston, Texas.—p. 1233.

*Macrocytic Anemia, Other Than Pernicious Anemia, Associated with Lesions of the Gastrointestinal Tract. C. C. Sturgis and S. M. Goldhamer, Ann Arbor, Mich.—p. 1245.

Tolerance and Toxicity of Insulin. II. With Forced Administration of Carbohydrate. F. M. Allen, New York.—p. 1263.

Psychotherapy, with Special Reference to Use of Hypnosis. J. L. McCartney, Philadelphia.—p. 1279.

The Problem of Rheumatism and Arthritis. Review of American and English Literature for 1937 (Fifth Rheumatism Review). P. S. Hench, Rochester, Minn., W. Bauer, Boston, M. H. Dawson, New York, F. Hall, Boston; W. P. Holbrook, Tucson, Ariz., and J. A. Key, St. Louis.—p. 1295.

Chronic Brucellosis in School Children.—Angle and Algie found evidence of chronic illness (the persistence of any two of the following symptoms: nervousness, headache, rheumatic symptoms or constipation) in 179 of the 462 positive brucellergin reactors, negative tuberculin reactors studied in 1937. The symptoms persisted in 57.5 per cent of the 139 children reexamined in 1938. Control studies indicated that there was a higher percentage of children with chronic illness in the group under investigation. Replies received from twenty-six professors of immunology indicated that the presence of agglutinins, opsonins and allergic cutaneous tests are specific reactions for present or past Brucella infection. Immunologic evidence of Brucella infection does not mean disease. The diagnosis of chronic brucellosis depends on clinical signs plus some positive laboratory data. The ambulatory and subclinical types of Brucella infection are apparently not uncommon.

Macrocytic Anemia Associated with Gastrointestinal Lesions.—During the last eleven years Sturgis and Goldhamer have observed a large group of patients with pernicious anemia during the course of which they encountered a number of patients with macrocytic anemia who illustrate strikingly the various types of gastrointestinal lesions which may cause such an alteration in the blood. One reason which indicates that intestinal lesions are responsible for this type of anemia is the disappearance of the anemia when the intestinal lesion is repaired. In one case, for example, the erythrocyte count returned to normal following resection of the small intestine for partial obstruction, at which time the patient was not receiving any antianemic therapy. It is also of significance that the anemia reappeared when the partial obstruction recurred. Further evidence that the group of patients which was studied did not have a true addisonian anemia which by chance was associated with some gastrointestinal lesions is that in three of the ten patients considered free hydrochloric acid was present in the gastric secretions. Also five of the remaining seven patients did not have paresthesia of the hands and feet, which is present in 90 per cent of patients with pernicious anemia. Furthermore, only one patient had recurrent glossitis, which is present in approximately 65 per cent of patients with addisonian anemia. Atrophy of the tongue was not present in the eight patients in whom this sign was looked for. This sign is present in about half of the patients with pernicious anemia. It is not difficult

to understand why a macrocytic anemia develops in some patients following partial resection of the stomach. The intrinsic factor which is essential to maturation of the erythrocytes is undoubtedly secreted by the glands in the gastric mucosa. It appears to be a logical assumption that the development of a macrocytic anemia following operations on the stomach depends almost entirely on how much of the stomach remains following the operation. The association of this type of anemia with the presence in patients of multiple intestinal anastomoses can readily be explained on the ground that the intestinal contents may pass through only a small portion of the small intestine in such cases and, therefore, the likelihood of absorbing a normal amount of the active principle would be diminished. It is somewhat more difficult to understand why this type of anemia should develop in a patient with an intestinal stricture or partial obstruction, such as existed in one of the present cases, as only a relatively small portion of the small intestine was involved in the pathologic process. A plausible assumption would be that even a localized lesion may in some manner affect the entire intestinal tract in such a way as to destroy or prevent the absorption of the active principle. It appears that from two to five years is required for macrocytic anemia to develop following resection of the stomach, that is, to reach a stage severe enough to produce symptoms. The length of time elapsing varies according to several factors. First, it is dependent on the extent to which the gastric and intestinal function is impaired; secondly, it is affected by the amount of reserve erythrocyte maturing material which is stored in the liver and perhaps elsewhere in the body. Other conditions which may possibly be of importance are the age of the patient and the presence of infections. For example, the reserve supply of the active principle would be consumed more rapidly in an elderly patient than in a younger one or in one with an active infection, and on this account a macrocytic anemia would develop more quickly in such a patient.

Gliomas of the Pons: Clinical and Pathologic Characteristics. B. J. Alpers and J. C. Yaskin, Philadelphia.—p. 435.

Pathologic Picture of Thujone and Monobromated Camphor Convulsions: Comparison with Pathologic Picture of Human Epilepsy. L. Opper, New Haven, Conn.—p. 460.

"Silver Cells" and "Spirochete-like" Formations in Multiple Sclerosis and Other Diseases of the Central Nervous System. G. B. Hassin and I. B. Diamond, Chicago.—p. 471.

Quantitative Absorption of Phenolsulfonphthalein from Subarachnoid Space. W. J. Gardner and W. A. Nosik, Cleveland.—p. 484.

*Return of Cognitive Conscious Functions After Convulsions Induced with Metrazol. L. H. Cohen, Worcester, Mass.—p. 489.

Ligation of the Left Anterior Cerebral Artery: Its Hazards and Means of Avoidance of Its Complications. J. L. Poppen, Boston.—p. 495.

Action of Metrazol (Pentamethylenetetrazol) on Hypothalamus of the Cat. J. H. Masserman, with technical assistance of E. W. Haertig, Chicago.—p. 504.

Cardiac Activity During Epileptic Seizures. T. C. Erickson, Montreal.—p. 511.

*Electro-Encephalography in Clinical Neurology: Its Value in Routine Diagnosis. D. Williams, London, England, and F. A. Gibbs, Boston.—p. 519.

Neurogenic Tumors Arising from the Sacrum. A. W. Adson, F. P. Moersch and J. W. Kernohan, Rochester, Minn.—p. 535.

Localized Nonsuppurative Encephalitis Adjacent to a Focus of Infection in the Skull. M. Atkinson, New York.—p. 556.

*Tuberous Sclerosis: Relief of Epileptic Symptoms by Radiation Therapy. A. B. Friedman, Brooklyn.—p. 565.

Analysis of the Thinking Disorder in a Case of Schizophrenia. Eugenia Panfmann, Chicago.—p. 568.

Bilateral Frontal Lobectomy: Follow-Up Report of Case. R. M. Brickner, New York.—p. 580.

Sign of Facial Palsy. R. Wartenberg, San Francisco.—p. 586.

Return of Consciousness After Induced Convulsions.—Cohen studied the return of the cognitive conscious functions in the period following convulsive seizures. The studies were carried out on schizophrenic patients during metrazol therapy. The functions of esthesia, prosexia, gnosia, praxia and mnesia reappear in the order given. It is suggested that these studies be extended, since they have a bearing on the general problem of the nature of consciousness. Furthermore, it appears that metrazol offers a safe and convenient means for the study of the interruption and normalization of the stream of consciousness.

Electro-Encephalography in Clinical Neurology.—Williams and Gibbs state that the electro-encephalogram has been used in the routine investigation of patients in a large neurologic and neurosurgical service over a period of ten months. The site and character of foci of abnormal cortical rhythms were determined by the method described by Walter. In 105 cases in which intracranial lesions were suspected there was a close correlation between the actual position of the lesions and that predicted by the electro-encephalograms in the fifty cases in which the pathologic process was demonstrated. The lesion was demonstrated at operation or necropsy in thirty-five of these fifty cases, and in another fifteen cases clinical evidence of localization was strong or was supported by the results of previous exploration, by x-ray evidence or by other signs of the lesion, such as a visible mass, skull defect or scalp wound, so that the diagnosis could be made with accuracy. In forty-one cases in which no cerebral lesion was demonstrated in the electro-encephalograms, subsequent clinical investigation gave negative results. In the remaining fourteen cases the position of predicted cerebral lesions could not be confirmed through lack of clinical and pathologic data. It is concluded that the method has great practical value as a diagnostic procedure in routine neurologic practice.

Tuberous Sclerosis.—Friedman reports a case of tuberous sclerosis without mental deterioration treated with roentgen rays. The epileptic symptoms were relieved. The patient has remained well for more than two and a half years.

Archives of Surgery, Chicago

38: 397-598 (March) 1939

Congenital Cystic Dilatation of the Bile and Pancreatic Ducts: Necropsy Thirteen Years After Hepaticoduodenostomy. G. L. McWhorter, Chicago.—p. 397.

Clinical Significance of Calorimetric Changes in the Lower Extremity. B. Lipshutz and M. Naide, Philadelphia.—p. 412.

Intracranial Hypertension of Unknown Cause: Cerebral Edema. A. L. Sahs and O. R. Hyndman, Iowa City.—p. 428.

Swelling of the Brain in Cases of Injury to the Head. P. Shapiro and H. Jackson, Chicago.—p. 443.

Experimental Production of Tumors of the Brain with Shope Rabbit Papilloma. B. Woodhall, R. W. Graves and J. W. Beard, Durham, N. C.—p. 457.

The Superior Colliculi: Their Function as Estimated from a Case of Tumor. O. R. Hyndman and W. J. Dulin, Iowa City.—p. 471.

*Hemangioma of Joints: Report of Five Cases. G. E. Bennett and M. C. Cobey, Baltimore.—p. 487.

Atresia Ani Urethralis: Report of Case. L. A. Thumig, Brooklyn.—p. 501.

*Ethyl Alcohol as Germicide. P. B. Price, Baltimore.—p. 528.

Parathyroidectomy for Raynaud's Disease and Scleroderma: Late Results. Alice R. Bernheim and J. H. Garlock, New York.—p. 543.

Regional Redistribution of Blood in Experimental Secondary Shock. H. A. Davis, Memphis, Tenn., and R. J. Jermstad, St. Joseph, Mo.—p. 556.

Review of Urologic Surgery. A. J. Scholl, Los Angeles; F. Hinman, San Francisco; A. von Lichtenberg, Budapest, Hungary; A. B. Hepler, Seattle; R. Gutierrez, New York; G. J. Thompson and J. T. Priestley, Rochester, Minn.; E. Wildbolz, Berne, Switzerland, and V. J. O'Conor, Chicago.—p. 581.

Hemangioma of Joints.—Bennett and Cobey present five cases of hemangioma of the knee joint. The age at onset varied from 18 months to 18 years and the duration of symptoms from ninety minutes to eight years. Trauma was not a factor. Swelling was present in all cases, with pain and recurring attacks of limp and pain on motion in four. The palpable elastic, spongy mass, compressible and distensible, was evident in only two. There was tenderness in two. Muscular atrophy and crepitation were present in only one case. Two of the patients received no treatment before operation, two were treated with rest in bed and one was treated with bandages and casts. The roentgenograms throughout failed to show any abnormality except for erosion of the cartilage in one case. In the first case complete excision was attempted, hemorrhage and infection followed, and finally amputation had to be performed. Complete excision was possible in only one case, in which the tumor was pedunculated. Biopsy followed by radium or roentgen therapy was carried out in the other three cases, with practically complete recovery. The final diagnosis of hemangioma was made and verified by

histologic study in the first four cases. The signs, symptoms and course made the diagnosis certain in the last case.

Ethyl Alcohol as Germicide.—Using original quantitative tests of bactericidal activity, Price has found ethyl alcohol, within certain narrow limits of concentration, to be strongly germicidal, both in vitro and on the skin. Exactly 70 per cent by weight (which has no constant volume per cent equivalent) is the most effective concentration. Even slight variations from this particular strength lessen its bactericidal power. Seventy per cent by volume is almost useless. Degermation of skin by alcohol takes place at a regularly logarithmic rate. Each minute the skin is kept in 70 per cent (by weight) solution without friction is equivalent to about six and one-half minutes of scrubbing in water. Friction increases the speed of degermation. Against test bacteria in suspension, 70 per cent (by weight) alcohol acts even more strongly and rapidly. Higher and lower concentrations are less effective. The difference between the degerming effects of alcohol on skin and in vitro are thought to be due largely, if not entirely, to differences in degree of contact between germicide and bacteria. This explains also why friction increases the germicidal action of alcohol on skin. Evaporation weakens 70 per cent alcohol and lessens its bactericidal power. A routine method of preoperative preparation of the hands has been evolved which, while simple, is a great deal more effective than technics in use at present in many leading hospitals. Seventy per cent by weight alcohol is recommended also for use in preparing the field of operation and in disinfecting contaminated hands.

Canadian Medical Association Journal, Montreal

40: 213-318 (March) 1939

*Prevention of Silicosis by Metallic Aluminum: H. J. J. Denny, W. D. Robson, Schumacher, Ont., and D. A. Irwin, Toronto.—p. 213.
Clinical Significance of a Lump in the Breast. E. M. Eberts, Montreal.—p. 228.
Leukoplakia and Allied Mouth Conditions. D. Quick, New York.—p. 234.
Low Back Pain and Sciatica. J. A. L. Walker, Windsor, Ont.—p. 240.
Carcinoma of the Sigmoid Colon (Radiologic Study). A. C. Singleton and M. R. Hall, Toronto.—p. 247.
*Abolition of Clinical Tuberculosis by Anticipation and Control. W. Ogden, in collaboration with G. C. Anglin, M. Brown, A. H. W. Caulfeild, Edith Gordon, T. G. Heaton, W. C. Kruger, E. L. Sexsmith, Margaret S. Thompson and T. R. Welwood, Toronto.—p. 253.
Diabetes Mellitus with Marked Hypercholesterolemia and Signs Simulating Cerebral Thrombosis. Case. I. M. Rabinowitch, Montreal.—p. 257.
Changing Conditions for Cesarean Section. R. T. Weaver, Hamilton, Ont.—p. 259.
Hernia. R. K. Magee, Peterborough, Ont.—p. 264.
Intravenous Glucose Tolerance Curve as Index of Liver Function and Liver Replacement Therapy in Cases of Hepatic Insufficiency. R. Wilson, Vancouver, B. C.—p. 268.

Prevention of Silicosis by Metallic Aluminum.—In a previous article Denny and his co-workers showed that the addition of small quantities of metallic aluminum powder almost completely inhibited the solubility of silicious material in the beaker. Silicosis developed in six rabbits exposed to quartz dust for six months. The condition did not develop in seven rabbits exposed to quartz dust plus 1 per cent metallic aluminum powder for the same period. The authors state that metallic aluminum on being converted into hydrated aluminum reduces the toxicity of quartz in tissues by flocculation, by absorbing silica from solution, but chiefly by coating the quartz particles with an insoluble and impermeable coating. This coating has been definitely identified as a gelatinous hydrated alumina, which on drying forms the crystalline alpha aluminum monohydrate boehmite. Other silicious materials when treated in a similar manner to quartz and aluminum in water appear to be coated by the precipitated gelatinous aluminum hydrate. Animals whose lungs on analysis contained 1 per cent or more of metallic aluminum have shown no evidence of silicosis after being exposed to quartz dust up to periods of seventeen and a half months. This was in direct contrast to well developed silicosis in the quartz control rabbits in seven months. In lungs having less than 1 per cent aluminum in which fibrosis is present there is no demonstrable evidence of hydrated aluminum in the fibrotic areas. In lungs in which the hydrated aluminum is shown on staining to be intimately and uniformly mixed with the silica particles, fibrosis has never been found. Aluminum dust for the prevention of silicosis should be of a particle size below 5 microns and grease free. It should be uniformly mixed in any inhaled dust and bear a definite percentage to this dust at all times. To prevent silicosis, aluminum dust may be inhaled daily independently of the silicious dust. The aluminum dust must be sufficiently concentrated in the inhaled dust to provide a minimum concentration in the lung of 1 per cent at all times. The inhalation of aluminum dust in large quantities over long periods of time showed no effect on the general health of the animals and no evidence of toxicity or damage to tissues. The concentration of aluminum dust necessary to prevent silicosis is hundreds of times below its explosive concentration.

Abolition of Clinical Tuberculosis.—Ogden and his collaborators present a plan for following contacts and normals through which an attempt is made to detect "preclinical tuberculosis," thus reducing the incidence of the disease and at the same time aiding diagnosis in the really minimal stages of those getting through the preclinical phase and acquiring actual disease. Over a period of fifteen years a total of 1,300 known contacts, tuberculin positive, and 400 normals have been under observation. Of those who followed the prescribed scheme, in not one has tuberculosis developed. When the contact series includes those whose observation was irregular, the disease developed in only 4.15 per cent (fifty-four) of the total. The incidence in other contact series ranges from 10 to 40 per cent, averaging from 20 to 25 per cent. Known tuberculosis contacts should be tested, first by tuberculin; then, if they are positive, this should be followed by serial serologic examination. All normals not known to be contacts should be tested, because exposure and infection frequently take place without contact being known. When they are tuberculin positive they are then serologically tested as contacts, because such they must have been. Serologic tests differentiate between those who are liable to develop tuberculosis and those who are not. Those thus found liable to develop tuberculous disease are advised accordingly.

Endocrinology, Los Angeles

Endocrinologic and Metabolic Observations in Exfoliative Dermatitis. W. J. Hanes and R. S. Crew, Philadelphia.—p. 404.
Present Day Status of Migraine Therapy. Mary E. O'Sullivan, New York.—p. 414.

Antidiuretic Substance in Urine in Eclampsia.—Teel and Reid state that concentrates prepared from the urine of preeclamptic and eclamptic women during the period of acute water retention exert marked antidiuretic effects on water diuresis in rats. The antidiuretic effect of a concentrate prepared from the

urine of an eclamptic patient after she had taken 1,400 cc. of water by mouth persisted. Similarly prepared concentrates from the urine of normal pregnant women during the last trimester of pregnancy and at the time of delivery exert little or no antidiuretic effect. However, if normal pregnant women are sufficiently dehydrated by withholding water, the urine contains amounts of antidiuretic substance comparable to those found in preeclamptic and eclamptic women. The antidiuretic principle recovered from the urine of preeclamptic and eclamptic women resembles solution of posterior pituitary. This substance acting on the kidney in abnormal amounts, or perhaps inadequately opposed by an antagonist, offers an immediate mechanism for the retention of water in preeclampsia and eclampsia.

Suppressive Action of Androgen on Menstruation.—The inhibitory action of the male hormone on human menstruation is illustrated by Papanicolaou and his associates by a case that they report. This is in accord with previous studies on lower mammals and primates. The absence of uterine bleeding and the persistence of an atrophic vaginal smear type during the period of treatment with the male hormone indicate that the cyclic uterine and vaginal functions were temporarily suppressed. Whether the male hormone acts directly on the ovaries or indirectly through its action on other endocrine glands is still uncertain. That menstrual functions can be inhibited in human beings by androgen, with the induction of a temporary sterility, is of considerable therapeutic significance. A beneficial effect on excessive and uncontrolled uterine bleeding has already been reported. This cessation of bleeding was associated with the development of an atrophic endometrium, an observation which has been subsequently confirmed. This endometrial atrophy is the uterine counterpart of the changes in the vaginal epithelium which underlie the atrophic vaginal smear that the authors observed following the administration of the male hormone. The hormone also appears to be of therapeutic help in the treatment of the menopausal syndrome. Once the atrophic smear is reached, the dose can be reduced to the minimal one which will maintain it. While the authors noticed no masculinizing effects of the male hormone in their patient, a recent study reports changes such as enlargement of the clitoris, marked vulval hyperemia and temporary lowering of the voice with intensive androgenic therapy. Menstruation occurred spontaneously in their patient twenty-eight days after androgenic therapy was stopped.

Treatment of Menopause with Androgen.—By the administration of from 30 to 50 mg. of testosterone propionate Kurzrok and his co-workers were able to ameliorate completely or almost completely the symptoms of the menopause in twenty-one cases. The substance produced no effect on the breasts, in that no patient complained of mastalgia. One patient with arthritis accompanying the menopause was benefited. There were no instances of itching or discharge due to the male sex hormone. Two cases of Trichomonas vaginalis infestation with pruritus responded to treatment with 25 per cent saline douches. Several of the younger women who had had a surgical menopause with resulting markedly severe symptoms responded fully as well as those in whom the menopause was spontaneous. One patient, with severe diabetes, was relieved of her flushes and sweats without any effect on the status of the diabetes. A few patients complained of localized pruritus on one occasion only, at the site of injection. Three patients had been treated previously with large doses of estradiol benzoate after a radiation menopause, with subsequent uterine bleeding; none of these women had any bleeding following administration of the male hormone.

Thyroid for Menstrual Irregularities.—Foster and Thornton treated fifty patients having menstrual irregularities with desiccated thyroid. The women have been observed for a period of from one to four years. Their ages have ranged from 16 to 34 years. With a few exceptions, only those who showed no pathologic changes in the pelvis have been treated. They all had basal metabolism rates below zero (from —1 to —33) the average being —15. Of the twenty-five patients with dysmenorrhea, seventeen had complete relief, five partial relief and three no relief. Of the seventeen patients with oligomenorrhea, all reported definite relief as long as they continued taking thyroid. Several of this group tried going without treatment during the summer vacation but returned in the fall asking to resume treatment because their symptoms had recurred. All stated that they felt much better when having their regular periods. The few patients in this series complaining of menorrhagia and metrorrhagia responded to thyroid therapy in a most satisfactory manner. Of four patients who complained of marked irritability prior to menstruation two obtained partial relief, enough so that they did not want to stop thyroid medication. One had complete relief and one noticed no difference. Thyroid was stopped several times but always with a recurrence of the symptoms.

Prothrombin Test and Vitamin K for Bleeding.—Olson reports the value of vitamin K in a patient who had been intermittently jaundiced for five months and apparently completely jaundiced for three months. Preoperatively, for obstruction of the common duct, she was given intravenous dextrose and a blood transfusion. At operation a diverticulum of the common duct was encountered and a calcareous obstruction at the ampulla of Vater was relieved. The duct was closed over a T tube, from which bile promptly flowed. Unusual bleeding was encountered at the time of operation and oozing occurred for several days after the operation. Six days after operation a severe hemorrhage occurred. This was controlled by a blood transfusion but the oozing recurred, and four days later another serious hemorrhage requiring transfusion again occurred. A prothrombin bleeding time after the method of Quick was 200 seconds. Vitamin K was given, two capsules being administered orally three times a day after meals. Each capsule was accompanied by 0.32 Gm. of bile salts. The prothrombin bleeding time was determined three days later and found to be 120 seconds. No further hemorrhage occurred and the oozing from the wound was decreasing. Seven days after the continued use of vitamin K the prothrombin bleeding time was reduced to thirty-eight seconds, which was comparable to a normal control, and all bleeding had stopped. The convalescence henceforth was uneventful. The author believes that, in jaundiced patients with an elevated prothrombin bleeding time, vitamin K should be administered prophylactically preoperatively and postoperatively until such time as the liver shall be able to elaborate concentrated bile into the intestinal tract and until such time as a balanced diet can be consumed.

Gonadotropic Content of Urine.—The Hellers determined the gonadotropic content of the urines from sixty-six menopausal patients. It was found that their potency was not related to the presence or absence of symptoms, age, hysterectomy or involution. No difference in gonadotropic potency was found

between menopausal women with symptoms and senile women, castrated women or menopausal women without symptoms. Urinary gonadotropic concentration was low in women with regular normal menstrual cycles, high in menopausal women in whom cycles had ceased and intermediate in menopausal women with irregular cycles. Treatment with estrogen alleviated the vasomotor symptoms of fifteen menopausal women but failed to reduce their gonadotropic potency concurrently. Continued treatment with estrogen caused a slight reduction in potency but failed to suppress it by significant amounts.

Rheumatic Manifestations in Relatives of Rheumatic Patients.—Gauld and his colleagues studied the high incidence of rheumatic disease in the families of ninety-six rheumatic children. The percentage of persons with a rheumatic history who had parents with a similar history was found to be consistent in two generations of these families and was 3.7 times as high as was found in the families of a control group of normal children. The offspring of the grandparents of the rheumatic and control persons were studied to see whether any relationship was present between the type of mating with respect to rheumatic disease and the percentage of children who were rheumatic. When one or both parents had a history of rheumatic manifestations (rheumatic fever or carditis or chorea) a greater percentage of the offspring was rheumatic than was found in the offspring of parents who had no history of rheumatic disease. The percentage of rheumatic manifestations was found to be almost twice as high in female offspring of rheumatic mothers as in the male offspring of these mothers. A greater percentage of persons with rheumatic disease was found among the maternal aunts and uncles than was found among the paternal aunts and uncles of the rheumatic cases. The data suggest that a hereditary constitution may play a part in the predisposition to this disease. The evidence, however, does not exclude the possibility that infection plays an important part and that exposure may be the predominating factor.

Complement Fixation in Human Malaria.—Eaton and Coggeshall describe complement fixation studies the antigens for which were prepared from (1) normal monkey red cells, (2) parasitized red cells of monkeys dying with Plasmodium knowlesi infection and (3) the spleens of monkeys dying with Plasmodium knowlesi infection. The serums were obtained from (1) normal human beings, (2) patients with syphilis, (3) patients with dementia paralytica who were receiving malaria therapy and (4) patients with malaria alone. The malarial antigens gave negative complement fixation reactions with from 70 to 80 per cent of the syphilitic and normal serums and weak or doubtful reactions with the remaining 20 to 30 per cent. With the exception of one antigen prepared from spleen, there was no evidence that the malarial antigens were more reactive with Wassermann-positive than with Wassermann-negative serums. Some human serums gave weak complement fixation with antigens prepared from normal monkey erythrocytes and the percentage of these positive reactions was slightly higher with malarial serums than with normal or syphilitic serums. The most sensitive and specific malarial antigen was prepared from dried parasitized red cells by extraction with saline solution, freezing and thawing. This Plasmodium knowlesi antigen gave strong complement fixation with malarial serums from human beings infected with Plasmodium knowlesi, Plasmodium vivax or Plasmodium falciparum. The titer of complement fixing antibodies reaches a maximum about one month after the beginning of the acute infection. At this time all of the Plasmodium knowlesi serums tested were positive. After four months the reaction diminishes rapidly in titer but may remain positive for twelve months or longer. With Plasmodium knowlesi infections in man, the complement fixation reaction remains positive for some time after the infection has apparently disappeared as judged by daily smears and inoculation of monkeys with the blood. The complement fixation reaction in malaria is group specific rather than species specific. Serums from patients infected with Plasmodium vivax or Plasmodium falciparum reacted in the same way with the Plasmodium knowlesi antigen as the homologous serums. Absorption of malarial human serums with normal monkey erythrocytes does not remove the immune bodies which fix complement with malarial antigens.

Effects of Quinidine Sulfate in Children.—Messeloff studied the effects of various doses of quinidine sulfate on ten children with regular sinus rhythm, one with frequent and persistent premature auricular contractions and one with bundle branch block associated with congenital heart disease. The impairment of auriculoventricular and intraventricular conduction as well as a decrease in the amplitude of the positive T wave, phenomena noted in adult studies, are also seen in children. The principles of dosage and of cumulation governing the clinical use of the drug in children appear to be identical with those reported in adults. Intraventricular conduction in the child with the bundle branch block was not unduly impaired by quinidine. Children tolerate large doses of quinidine, as judged by the age and weight standards. The usual adult daily dose of from 15 to 30 grains (1 to 2 Gm.) may be safely given to children. However, the large doses should be controlled by frequent electrocardiograms. The principles underlying dosage and cumulation of quinidine established for adults apply equally to children.

Effects of Tobacco Smoking on Health.—In an attempt to learn what, if any, symptoms are produced in comparatively healthy ambulatory persons by the use of tobacco, Short and his co-workers asked an unselected group of insurance policy holders to fill out a questionnaire, at the time of their periodic health examination, designed to elicit their practices with reference to the use of tobacco, but contained no reference to physical signs or symptoms. The latter information was obtained independently from the physical examination and medical history, which were recorded separately. Of 2,031 persons studied, 1,292

habitually used tobacco, 496 were nonusers, 104 used it only occasionally and 139 were former users who had discontinued the practice. Symptoms relating to the respiratory, circulatory, gastrointestinal and nervous systems were definitely increased among smokers. These increases ranged from 50 per cent for palpitation of the heart to 300 per cent for cough. The increased tendency to dyspnea on exertion in smokers gives point to the tabu on tobacco by many athletic directors, especially the trainers of pugilists. The relationship of tobacco smoking to gastric disturbances, especially hyperacidity, is a frequent clinical observation. For this reason sufferers from gastric or duodenal ulcers are usually asked to refrain from tobacco. In this study "heartburn" was increased by 100 per cent, and other digestive symptoms from 62 to 112 per cent. There was no significant variation between the smokers and nonsmokers in weight, pulse rate or blood pressure. Tremors appeared to be diminished in the smoking group. However, there was a tendency for tremors to be increased if habitual users were deprived of tobacco for a time; also blood pressures tended to vary considerably during the actual process of smoking. Seventy-eight of the 139 persons who gave up smoking did so for reasons of health.

Reactions to Tobacco Smoke and Epinephrine.—Short and Johnson made a direct comparison of the effects of epinephrine injection with those of tobacco smoking. Their observations, they state, confirm the view that the characteristic effects on pulse, blood pressure, peripheral cutaneous temperature and blood sugar of tobacco smoking can be explained by an increased output of epinephrine. This most probably is the result of a stimulating effect of nicotine on the sympathetico-adrenal system.

Transurethral Operations for Dysfunction of Vesical Neck.—Thompson performed thirty-five transurethral operations for dysfunction of the vesical neck among twenty-four women. The etiology of this disease is not definitely revealed by microscopic study of the tissue removed at operation. The hypothesis that it is caused by fibrosis in the sphincteric region seems fallacious in view of the fact that a considerable amount of fibrosis is found in normal tissue from this region. A possible explanation is that hyperplasia of the superficially lying epithelium or of the sphincter muscle occurs and causes urinary retention. The results of operation were excellent in fourteen cases, good in five, fair in four and poor in one. Removal of tissue from the entire circumference of the vesical neck is necessary to obtain a good result in all but exceptional cases in which only incision might suffice. The patient should be observed for a number of years following operation, and treatment including dilation with a Kollmann dilator will probably be necessary in some cases in order to maintain normal vesical function; the transurethral operation can be repeated with benefit if urinary obstruction recurs.

Vitamin C and Essential Hematuria.—Burkland used vitamin C in the treatment of four cases of essential hematuria. There was no evidence of scurvy or gross vitamin C deficiency in the four patients, except possibly in one who had colitis and diarrhea for some time. Yet the hematuria, which in each case had been present for several weeks, disappeared after the patients were given intravenous injections of vitamin C in the form of the sodium salt of ascorbic acid in sterile water. The dosages were arbitrarily chosen and therefore varied in patients from 100 to 300 mg. daily. A decrease in the hematuria occurred on the oral administration of vitamin C in the form of ascorbic acid tablets and fruit juices, but the intravenous administration was necessary to produce a more rapid, dramatic response. This was probably because on oral medication the absorption is delayed and is often faulty. It is the author's opinion that the vitamin C stopped the hematuria through its ability to cause alteration in capillary permeability, but, in addition, other actions reputed to it, such as increasing the coagulability of the blood, stimulating epinephrine secretion and acting as a catalyst for cellular metabolism, may have played some part in causing cessation of the hematuria. The effect may also be due to the fact that in the utilization of vitamin C by the body a large amount of it is excreted by the kidneys, leading to a high concentration in these organs. In view of the efficacy of the treatment, cases of essential hematuria might be considered as subclinical forms of vitamin C deficiency.

*Mumps Meningo-Encephalitis. T. L. Birnberg, St. Paul.—p. 173.

Progesterone for Habitual Abortion.—During the last year Peters has treated four cases of recurrent spontaneous abortion. The patients delivered normal living infants at term. As soon as the diagnosis of pregnancy was made and up to and

including the fifth month of pregnancy the patients received biweekly intramuscular injection of progesterone or corpus luteum extracts amounting to approximately 1 international unit. In all cases the blood Wassermann reactions were negative and nothing in the history, physical examination or laboratory data could be found to account for the abortions. No definite conclusions can be stated, but the author makes the suggestion that progesterone is a specific for a certain type of quite common recurrent abortion and premature labor, a view which is corroborated by experimental studies.

Mumps Meningo-Encephalitis.—*During a period of five* and a half years Birnberg has encountered thirty-eight cases of mumps meningo-encephalitis in private practice. So large an incidence, with no coincidental unusual mumps epidemic, leads him to consider mumps as a disease in which meningeal symptoms appear relatively often, and in the preadolescent age group it has been the most frequent complication that he has observed. The specific cause of mumps meningo-encephalitis would seem to be either the mumps virus or a toxin liberated by the virus. The clinical symptoms of mumps meningo-encephalitis may appear at from one to ten days after the onset of the parotitis. Occasionally the meningitis and parotitis develop simultaneously, as in one of the present cases. The neurologic symptoms in rare instances precede the parotitis by several days. There are some cases in which the meningo-encephalitis would appear to be of undoubted mumps origin by virtue of epidemiologic contact but in which a parotitis never occurs or is so slight as to pass unnoticed. The symptomatology, as observed in the thirty-eight cases, shows a fair degree of uniformity. The presenting symptom is almost invariably headache, often quite intense. Vomiting occurred in practically all cases but was usually not incessant and persisted for only one or two days. All patients had varying degrees of fever. Hiccup, lethargy or irritability were inconstant and usually not pronounced symptoms. Rarely dilated pupils may be an index of cerebral involvement. Convulsions and focal paralysis have been recorded but the author did not observe them in his cases. Neurologic examination almost always reveals rigidity of the neck and a positive Kernig sign. The diagnosis rests largely on the recognition that such a complication does occur. The relatively mild symptoms with a rather high cell count are a valuable diagnostic criterion. The treatment of mumps meningo-encephalitis is chiefly symptomatic. Spinal puncture should be performed as a diagnostic procedure; it is often of value in reducing fluid pressure, particularly in patients with persistent headache and vomiting. Mumps meningo-encephalitis persists for from three to eleven days. The temperature returns to normal and the subjective symptoms clear up two or three days before the neurologic signs become normal.

Alcohol Tolerance Tests in Normal and Diabetic Persons.—Blotner discusses the results of some alcohol tolerance tests that he performed on normal persons and on patients with diabetes insipidus and diabetes mellitus following the ingestion of 0.6 cc. of absolute alcohol per kilogram of body weight. He also studied the effect of insulin, solution of posterior pituitary, food and forced water intake on these tests. Symptoms of alcoholic intoxication appeared in these people when the alcohol concentration of the blood and the urine were below 63 mg. per hundred cubic centimeters, in comparison to the much higher levels reported by others. Alcohol curves of the blood and the urine after a test meal were slightly higher in patients with diabetes insipidus than in normal persons. Solution of posterior pituitary reduced the alcohol levels of the blood and the urine in both these groups; nevertheless it increased considerably the symptoms of alcoholic intoxication in the former. In the patients with diabetes mellitus the alcohol levels of the blood and the urine were appreciably higher than normal, although the symptoms of alcoholic intoxication were much the same. The administration of insulin had no effect on the alcohol curves or on the symptoms of alcoholic intoxication. An alcoholic odor on the breath may cause confusion in the diagnosis of coma due to insulin or acidosis. The ingestion of food before the ingestion of alcohol produced a striking decrease in the alcohol levels of the blood and urine and in the symptoms of alcoholic intoxication in diabetic patients. The diuresis resulting from forced water intake and uncontrolled diabetes insipidus did not dilute the concentration of alcohol in the urine but increased the total amount of alcohol excreted in it. Nevertheless, forcing water in the case of an alcoholic patient would not produce any appreciable results in therapy, because the total alcohol eliminated by this method is small compared to the amount ingested.

*Use of Specific Serums in Treatment of Pneumonias Associated with Pneumococci of the "Higher" Types. M. Finland, Boston.—p. 336.
Gastro-Enterology. C. M. Jones, Boston.—p. 339.

Serums for Pneumonias of "Higher" Types.—Finland believes that type V, VII and VIII pneumonia is sufficiently prevalent to make it possible to accumulate significant numbers of cases within a reasonable time to indicate the efficacy of any therapy. Pneumonias due to the "higher" types may be quite atypical in their symptomatology and in the character of the

pulmonary lesions produced. This is in sharp contrast to types I and II, which except in rare cases are associated with typical lobar pneumonias. Thus a small percentage of cases of type V pneumonia are atypical, but among those due to types VII and VIII, particularly the latter, the disease may be atypical in a considerable proportion of cases. The experience of all observers who have treated any appreciable number of cases of type V pneumonia with serums has been uniformly favorable. In most clinics, including the Boston City Hospital, the results as judged by the reduction in mortality and the occurrence of rapid clinical improvement have been comparable to those obtained in type I cases or even better. Experiences with type VII and VIII cases, on the other hand, have varied widely; most of them have been favorable, and the mortality in specifically treated cases has been lower than that of non-serum treated cases. One may also include type XIV pneumonia in infants and young children among those which have given favorable results in clinics in which serum has been used extensively. There are many fundamental reasons underlying the differences in result, and these are in no way different from the circumstances previously encountered in type I and II cases. Therefore every effort should be made to acquire the necessary basic information with regard to the frequency of the various types in pneumonia, the bacteremic incidence, the death rates among the various types of pneumonia and the occurrence of the same types of pneumococci in the respiratory tract under other conditions. In acutely sick patients with good sputum raised from the bronchi, particularly if it is rusty, the discovery of a given type as the only or definitely predominating organism is adequate indication for specific serum, and its proper employment will probably increase the chances of rapid recovery. Further experience may reveal that certain of the types are more regularly and intimately related to pneumonia than are others. Already it appears that a greater proportion of types IV, XII and XVIII pneumococci, for example, are causative agents in pneumonia than are those of types VI, X, XX and types "higher" than XX. This is only relatively true, however, since probably every type may cause severe and even fatal pneumonia under the proper circumstances or in a particular individual.

Ito Test for Chancroid.—Saunders and his associates believe that the Ito test, performed with vaccines of Ducrey streptobacilli, is specially valuable in the diagnosis of long-standing chancroids. In the majority of these phagedenic lesions, in which autoinoculations are usually negative, the Ito test is always positive. The negative autoinoculations in these cases are probably due to the overgrowth of the Ducrey streptobacillus by common pyogenic bacteria. They substantiate the opinions of other observers that the Ducrey vaccine is satisfactory as a diagnostic test in the majority of cases. In a comparison of Greenblatt's vaccine with dmelcos, 180 tests were performed on eighty-six individuals. The tests were positive in forty-four cases and negative to both vaccines in forty-six cases. In twenty-six of the positive cases the two vaccines gave equal reactions. Greenblatt's vaccine gave stronger reactions than dmelcos in four cases and weaker reactions in sixteen cases. A comparison of an American commercial vaccine with dmelcos (sixty-two tests on twenty-seven persons) gave nineteen negative and twelve positive reactions with both vaccines. In five of the positive cases the two vaccines gave equal reactions. The commercial vaccine was stronger in one case and weaker in six cases. In comparing the three vaccines, 360 tests were performed on 112 persons; seventy-six gave negative reactions to all vaccines, forty-four gave positive reactions, of which twenty-six were of equal intensity, and eight gave the strongest reaction with dmelcos, four with Greenblatt's and four with the commercial vaccine. When the reaction to dmelcos vaccine was negative, the other two vaccines also gave negative reactions. The differences in the positive reactions were slight and in no case of such a degree as to be of any practical value. Therefore the specificity of the two American Ducrey vaccines for the diagnosis of chancroidal infections is confirmed.

Dextrose Tolerance in Rheumatic Fever.—Schultz obtained curves indicating the degree of dextrose tolerance in ten patients with rheumatic fever and fourteen with various febrile diseases. In none of the patients is it apparent that the patient with rheumatic fever, in comparison with those suffering from other febrile diseases, possessed an increased degree of dextrose tolerance. However, in comparison four rheumatic patients showed a relatively decreased dextrose tolerance. This may perhaps be accounted for by the occurrence of slightly higher temperatures in the rheumatic fever patients in some instances. In both groups temperatures had been closely comparable during preceding days and, with the exception of one comparison, the erythrocyte sedimentation rates agreed closely. On the basis of dextrose tolerance tests the author states that no association between rheumatic fever and hyperinsulinism is demonstrable.

Common Animal Parasites Transmissible to Man.—Endamoeba histolytica, Trichomonas hominis, Ascaris lumbricoides and Enterobius vermicularis, according to Mugrage, are endemic in the vicinity of Colorado and he believes that more frequent stool examinations in the laboratory would undoubtedly disclose other parasites. Animal parasites seldom seen now may be encountered in the future owing to the increasing use of rapid transportation, the airplane particularly. Any person coming from a country in which animal parasites are prevalent is potentially a carrier. Animals or birds brought in, or even the airplane, automobile, ship or baggage can also

act in a similar way. With rapid transportation the incubation period for development of the parasite may extend beyond the time of arrival of the host at his destination, with subsequent development of symptoms not diagnosed unless this possibility is considered. A few cases of malaria have been seen at Colorado General Hospital with symptoms developing after the person's return to Colorado from the South. The United States Public Health Service considers this possibility a definite problem, and its personnel inspects both passengers and airplanes on all commercial airlines coming into this country. The Army and Navy medical corps also consider animal parasites of major importance in their problems on health and sanitation and their medical schools stress this subject. Other governmental departments are also active on this public health problem of parasite control, which the medical profession in general practice has largely slighted.

Action of Sodium Thiocyanate on Hypertension.—Doles studied the value of the thiocyanates by giving ten patients with hypertension and macrocytosis a general diet with an intake of 30 mg. of iron daily through food and water. After the fifth day the output of iron in twenty-four hours was estimated in the stools and urine for four days. The average daily output was from 14.5 to 16 mg. The patients were then given a diet in which the maximal intake of iron in twenty-four hours did not exceed 7.5 mg. and after the fifth day quantitative determinations were made for five consecutive days. Only a faint trace of iron could be found in the stools and none in the urine. The same procedure was carried out with this diet being continued and the patient was given 3 drachms (12 Gm.) of sodium thiocyanate twice a day. From 12.5 to 24.5 mg. of iron, depending on the patient, was recovered in the stools and urine every twenty-four hours. As long as the patient showed a relatively high output of iron in the stools and urine there was a fall in the volume of packed cells with a corresponding fall in the blood pressure. However, four patients did not give up their iron readily; and it was many months before the macrocytosis or blood pressure responded. Contraindications to the use of thiocyanates are hypertension in which the cells are normocytic, normochromic, normocytic hypochromic, microcytic normochromic or microcytic hypochromic, or in macrocytic hypertensions which show an increase in the icterus index of 7 units or more without evidence of hepatic disease.

Castor Oil for Dermatoses of Intestinal Origin.—Schoch treated ten patients who had dermatoses presumably of intestinal origin with castor oil by mouth or a castor oil derivative (sodium ricinoleate and kaolin emulsion). In nine there was clinical evidence that prompt benefit resulted from the administration of castor oil or its derivative. Not the slightest benefit resulted from the administration of the castor oil in the remaining patient, even though the dermatosis was definitely intestinal in origin. Castor oil is probably more thorough in its cathartic action than the usually prescribed saline laxatives. The favorable influence that sodium ricinoleate apparently exerts in some cases is not clearly understood.

Multiple Primary Malignant Lesions.—From a review of the literature of the last twenty years, Stalker and his colleagues find that multiple primary malignant lesions occur more frequently than is generally suspected. They made a study of 2,500 cases of malignant lesions in which operation was performed at the Mayo Clinic during 1937. They found 113 instances of multiple primary neoplasms in this group of cases. In these cases there were 327 separate neoplasms; 167 involved the skin and lip, forty-seven of the neoplasms were situated in the gastrointestinal tract, forty-three in the mammary gland, twenty-seven in the ovaries and fourteen in the uterus or cervix, and twenty-nine were situated in various other parts of the body.

Fate of Living and Dead Cartilage.—Desiring to obtain more definite information concerning the fate of human cartilage grafts in human tissues, Peer performed the following experiments: 1. Six segments of cadaver cartilage preserved in alcohol were transplanted beneath the skin of six other human beings and removed for examination at intervals of from six months to two years. 2. Eight segments of living autogenous costal cartilage were buried beneath the skin of eight human beings and removed for examination at intervals of from six months to six years. All these grafts were transplanted without perichondrium. Dead cartilage grafts buried from nine and one-half months to two years showed progressive invasion by fibrous tissue and partial absorption. In contrast to this, autogenous rib cartilage grafts showed no invasion or absorption over the same period. Two late autogenous rib cartilage grafts buried for four and one half and six years, respectively, appeared as living cartilage. From the evidence found in these sections one may conclude that autogenous rib cartilage survives after transplantation as living cartilage and, up to periods as long as six years, neither increases nor decreases in size. Therefore autogenous rib cartilage is better material for plastic repair than dead, pickled cartilage.

Acute Arsenic Poisoning.—Besides the usual treatment of arsenic poisoning Porter used 800 international units of vitamin B_1 daily. The salient feature in the patients receiving the vitamin was the absence of diarrhea. It is his belief that the use of vitamin B_1 has a definite place in the treatment of toxic neuritis from metal poisoning. Prompt improvement of neuritic pains occurred after the vitamin B_1 had been administered for only a few days.

Recurrent Hyperthyroidism.—Cattell and Perkin relate the data of patients with recurrent or persistent hyperthyroidism observed at the Lahey Clinic in the last decade. They present evidence which suggests that the level of iodine in the blood in hyperthyroidism may be used as an index for determining the amount of thyroid tissue to be removed. Persistent hyperthyroidism results from not removing enough of the gland. Recurrent hyperthyroidism is a return of the primary disease at some time following operation, after an interval of complete relief from toxic symptoms. The causes of recurrent hyperthyroidism are as obscure as are the factors responsible for the original disease. From 1928 to 1937 inclusive subtotal thyroidectomy in one or more stages was performed on 4,956 patients. Of these patients 119 were later operated on for persistent hyperthyroidism and 187 for the recurrent type. The average time interval between the initial and second operation for persistent hyperthyroidism was two years and four months; for recurrent hyperthyroidism it was seven years and eleven months. The authors believe that following the initial thyroid operation recurrent hyperthyroidism can be often prevented if the patient is watched carefully. Their patients are advised to refrain from work for from six to twelve weeks. Daily periods of rest, avoidance of stimulants and excitement are necessary. Careful follow-up examinations including a basal metabolism test are done every three months for one year and every year for five years. At these examinations minor complaints are treated and general means are employed for rehabilitation. Follow-up study has led the authors to conclude that the use of iodine following subtotal thyroidectomy for hyperthyroidism did not reduce the incidence of recurrent or persistent hyperthyroidism. A study of the preoperative and postoperative blood iodine levels in 256 cases of exophthalmic goiter has given them a means of predicting cases in which recurrence is likely to happen. This prediction can be made prior to the initial thyroid resection and accordingly is a guide in selecting those patients who should have the more radical thyroidectomy. A correlation exists between the blood iodine level and the duration of symptoms in patients with exophthalmic goiter. The blood iodine level tends to be elevated in cases with symptoms of hyperthyroidism for nine months or less. After symptoms have been present for one year or longer the blood iodine level is generally found to be within normal limits. A further insight into the iodine metabolism in exophthalmic goiter has been gained by estimating the concentration of iodine in the blood at intervals following operation. Of 256 cases studied, 100 were followed for one year. The blood iodine results in these patients show that each case can be classified into one of three groups. Group 1 consists of 170 patients with hyperthyroidism who had an elevated blood iodine before treatment was commenced. Following subtotal thyroidectomy the blood iodine was found to remain normal throughout the year during which they were followed. Fifteen patients showed transitory postoperative myxedema, while only one had recurrent hyperthyroidism. Group 2 consists of sixty-one patients with hyperthyroidism who had a normal preoperative blood iodine level and following subtotal thyroidectomy were found to have an increase in the concentration of iodine in the blood. The greatest elevation of blood iodine usually occurred six months after operation. After one year the level of iodine in the blood returned to normal. Two patients of this group had transitory hypothyroidism, while twelve had recurrent hyperthyroidism. Group 3 consists of twenty-five patients in whom the blood iodine level was normal preoperatively and was found to remain normal during the year following subtotal thyroidectomy. Only one patient had transitory postoperative myxedema. Therefore it appears that in order to decrease the rate of recurrence in group 2 it becomes necessary to do a more radical subtotal thyroidectomy in all patients having a normal blood iodine level preoperatively.

Pellagra in Great Britain.—Davies and McGregor present a summary of the twelve cases reported as pellagra in Britain since 1934 and add four new cases seen by them. They believe that there is sufficient evidence to show that vitamin B_2 deficiency alone is not sufficient explanation for the occurrence of pellagra. Murray calls attention to the facts that maize is not inferior to rice or wheat in vitamin B_2 content, yet a rice diet rarely gives rise to pellagra, while a diet of maize often does, and that the consumption of yellow maize, in distinction to white, does not predispose to the disease. Again, many cases have been reported in which the diet previous to the onset of the disease was reasonably full and varied; the preponderance of the disease in the female sex also points to some additional factor besides vitamin deficiency. The former point is made much of by the exponents of the infective theory. The latter suggests the possible influence of the endocrines. Further, although Goldberger has shown that rat pellagra is purely a vitamin B_2 deficiency disease, variable only in relation to this deficiency, human pellagra shows an additional variation—a seasonal one. Sabry postulates a mother substance, or pellagratoxin, which is acted on by a ferment in the presence of sunlight to produce melanin. The mother substance is phenylalanine; he has identified the ferment as dopa-oxidase, which is present in maize and some other foods. Sabry injects thiosulfate, which, it is claimed, neutralizes the pellagratoxin. The exact part played by light, however, in producing the eruption is by no means clear. Crutchfield regards trauma of various kinds more important than any specific photodynamic action of the sun. Other substances besides vitamin B_2 are now known to have antipellagra properties. Chief among these is nicotinic acid. Though neither the maximal nor the minimal dose has been ascertained, the factor may well be administered in daily doses of 50 mg. Finally, there remains for discussion the possibility of an association between pellagra and Addison's disease. The connection has been proposed because of the frequent occurrence in pellagrins of symptoms suggestive of Addison's disease: hypotension, pigmentation, subnormal temperature, weakness and gastrointestinal upsets. According to Simpson, the situation may be epitomized as follows: 1. Vitamin deficiency might cause both pellagra and adrenal insufficiency in the same patient. 2. Adrenal insufficiency might occur in the course of pellagra as a sequel to malnutrition. 3. Pellagra might occur in the course of chronic Addison's disease as a sequel to the associated anorexia. In the present state of knowledge it would seem that no definite ruling can be given on the question of a direct etiologic association between the two conditions.

Life Expectancy After Ureteral Transplantation.—Wade states that, in order to determine the expectancy of life after ureteral transplantation and to assess accurately how far, if at all, this has been shortened by the establishment of a cloaca, it is necessary to select patients in sound general health and free of disease, but in whom the urinary bladder was irreparably damaged by developmental error or accident. In this category are included certain cases of complete vesical exstrophy, subsymphysial exstrophy and vesicovaginal fistula with destruction of the vesical sphincter from obstetric injuries or similar cause. Cases are now available in which a sufficient period has elapsed since ureteral transplantation to enable one to estimate accurately the influence of this operation on the general health of the patient and the expectancy of life. In this connection the author cites four cases in which the ureters were transplanted into the pelvic colon for the congenital malformation of vesical exstrophy. They demonstrate conclusively to him that when ureteral transplantation has been successfully performed the patient is given not only comfort, happiness and good health but also the prospect of a natural length of life. His patients were operated on thirty, twenty-eight, twelve and eleven years ago, respectively. This shows that only in those persons in whom a congenital deformity or traumatic injury is being corrected ureteral transplantation is a relatively safe procedure and fully warranted in these distressing disabilities.

Milk Epidemic of Scarlet Fever.—Henningsen and Ernst report a milk epidemic of scarlatinal angina. There were 118 cases of scarlet fever and about fifty cases of sore throat. The infection was spread through contamination of the milk from a milkmaid with purulent otitis media after nonrecognized scarlet fever. On cultivation, Streptococcus pyogenes, group A (Lancefield), type 3 (Griffith) was isolated from 108 of the patients and from pus from the ear of the milkmaid. The cows, on the other hand, and their milk were found to be normal. Inquiry into the conditions under which the milk was distributed to the consumers confirms the connection between the otitis media in the milkmaid and the epidemic of scarlet fever. The cases in this epidemic were mild, but still one patient died of complicating bronchopneumonia.

Treatment of Oriental Sore with Fuchsin.—Castellani and Amalfitano obtained satisfactory results with fuchsin paint in the treatment of three cases of cutaneous leishmaniasis. The fuchsin paint consists of 10 cc. of saturated alcoholic solution of basic fuchsin and 100 cc. of 5 per cent phenol solution. This is filtered and 1 Gm. of boric acid is added. After two hours 5 cc. of acetone is added, and still two hours later 10 Gm. of resorcinol is added. The solution is kept in dark stoppered bottles. The technic of treatment is as follows: For two days a dressing of boric acid (1 per cent) and resorcinol (1 per cent) is applied to the sore. The parts should be continuously kept moist with the lotion. This removes the crusts and scales present. Then the fuchsin paint is applied to the sore regularly twice a day and 2 cc. of the same solution is given intramuscularly every other day. The solution may also be injected into the nodule

and around it. Every eight or ten days the application of the fuchsin to the sore is discontinued for one or two days, when the boric acid and resorcinol dressing is again applied. The treatment effected a cure in the three cases reported in from two to three and one half months.

Treatment of Chronic Myeloid Leukemia.—Israëls cites seven cases of chronic myeloid leukemia in which myeloblasts appeared in the peripheral blood. When the patient with this disease has not received treatment, the presence of myeloblasts is not of serious significance if they disappear when roentgen therapy is begun. If they increase, the outlook is grave, irrespective of any changes in the total leukocyte count. When myeloblasts appear during treatment, they usually signify that roentgen therapy is no longer effective and that, whatever the total leukocyte count, death is imminent. The completeness of the myeloblastic transformation in the bone marrow is parallel to that in the peripheral blood. The effectiveness of treatment is best judged by the diminution of the proportion of immature leukocytes and by the improvement in the anemia. The anemia should be thoroughly treated and roentgen therapy may be postponed provided the immature leukocytes do not increase and the patient's clinical condition warrants it.

Urea Clearance in Hematemesis.—Black studied the renal function in twelve cases of gastrointestinal hemorrhage. The severity of the condition of some of these cases precluded the adoption of any disturbing procedure and principal reliance was placed on the urea clearance test of Van Slyke. In most of the cases there was a moderate or even a pronounced lowering of urea clearance; after a week the clearance usually rose to within normal limits. A "scatter diagram" was constructed, showing the relationship of urea clearance to red cell volume. Although four of the cases showed considerable divergence, the remainder approximate a linear relationship. This indicates some degree of correlation, in the present cases, between the urea clearance and the red cell volume; the divergent values indicate that other factors besides the red cell volume influence the clearance—a fact which is hardly surprising when one considers the wide normal variation in urea clearance. No correlation appears to exist between the urea clearance and the blood pressure, hemoglobulin or blood urea. After every allowance has been made for low protein intake and absence of diuresis, there is still evidence of diminished urea clearance in these cases. As pointed out by Van Slyke (1934), diminution of clearance must be due either to decreased renal blood flow or to less complete extraction of urea from the blood. The importance of blood flow is, however, suggested by the degree of correlation between the fall in clearance and the red cell volume. Estimations indicate some impairment of renal function. However, the present evidence is insufficient to establish definitely the mechanism of renal impairment.

Treatment of Tuberculosis in Children. J. Comby.—p. 168.

Treatment of Bronchopneumonias in Nurslings.—According to Soria, bronchopneumonia continues to be one of the diseases which have the greatest mortality rate in nurslings and young children. In nurslings its case fatality is more than 50 per cent. After pointing out that the mechanism of cellular and humoral defense is not yet organized in nurslings, the author discusses the various forms of bronchopneumonia such as the pulmonary, the cardiohepatic, the gastrointestinal, the nervous and the toxi-infectious form. The treatment of bronchopneumonia has remained unchanged in recent years and it must be admitted that until now there has been no specific and efficacious treatment. Some use serums and vaccines, others employ inhalation of oxygen, others autohemotherapy and still others physical therapy. The author uses hypertonic solution of dextrose (from 15 to 20 per cent), which exerts a regulating effect on the disordered metabolism and stimulates the organs in general, particularly the muscular fibers of the heart, increasing the nutrition of the muscle and restoring the tonicity, which had been damaged by the action of the toxins. The disturbances in the acid-base equilibrium of the nurslings with bronchopneumonia lead to a generalized atonia of the entire musculature, by glycogenic insufficiency, which produces a disturbance in the respiratory function and impairs the return of the blood to the general circulation; the result of this is a hypotension which can be observed in several of the aforementioned forms of bronchopneumonia. Muscular hypotonia can be brought about by a diminution of dextrose in the blood stream, also by a diminution of glycogen in the muscles and likewise by a sympathetic phenomenon. The favorable action of dextrose solution on the muscular tonus cannot be doubted. The arterial tension increases after the second or third injection, the pallor and cyanosis change to an almost normal coloration, the dyspnea diminishes, the diuresis increases, the patient becomes quieter and sleeps better, the thirst subsides, the loss of weight is gradually arrested and the appetite returns. In the cardiac form the author observed in addition to the improvement of the general condition also a decrease in the cardiac dilatation. The volume of the congested liver decreased and the pain disappeared. In the nervous form the results were not quite as surprising but the general condition and the arterial tension improved and drainage by lumbar puncture rapidly counteracted the nervous phenomena. In the gastrointestinal form, sugared water in a quantity of from 600 to 700 cc. (20 per cent maltose and dextrin) produced excellent results. In the toxi-infectious form, however, the hypertonic solution of dextrose does not produce such favorable results because of the virulence of the infection. These cases may terminate in death in the course of forty-eight hours. Of the various modes of administration the author regards the intraperitoneal route as the most suitable, pointing out that the left iliac fossa is the best site. He employs a needle from 5 to 7 cm. in length. Shock is avoided by injecting the dextrose solution with 0.5 cc. of a 1:1,000 solution of epinephrine hydrochloride. From 150 to 200 cc. of the dextrose solution is administered daily. The author employed this treatment in more than 150 cases and, as a result, the mortality decreased by from 30 to 35 per cent.

Rare Cases of Deviation of Cutaneous Allergy to Tuberculin in Tuberculous Children. G. Paisseau, J. Valtis and F. Van Deinse.—p. 307.
*Xenopus Pregnancy Test. E. Elkan.—p. 308.

Extraction of Projectiles from Heart.—Le Fort points out that it is now permissible to reply to the questions so often asked during the war of 1914 to 1918 regarding the immediate and late dangers caused by the presence of pro-

jectiles in the heart or by their extraction from the heart. He reviews the clinical histories of patients who underwent extraction of foreign bodies or projectiles from the heart more than twenty years ago and then discusses the various aspects of the extraction, such as indications for it, dangers involved and technic. In the conclusion he stresses that the extraction of foreign bodies is possible from the walls as well as from the cavities of the heart. The presence of free projectiles in the cavities of the heart involves considerable dangers, so that their removal is advisable. However, it should be undertaken with all necessary precautions. The projectiles which are enclosed in the cardiac walls do not seem to cause grave dangers. They may remain buried in the muscle without provoking grave anatomic lesions, but their presence is often accompanied by serious functional disturbances. The extraction of projectiles from the anterior wall is a simple operation. However, the extraction of projectiles from the postero-inferior wall is a complex procedure and may become extremely difficult in cases of cardiopericardiac symphysis. The small projectiles may be abandoned, provided they are well tolerated. The large ones and those which cause complications should be removed. The danger caused by the presence of a projectile in contact with the large vessels of the heart is less grave than is imagined. The author says that he demonstrated twenty years ago that the vessels defend themselves ordinarily against metallic foreign bodies either by enveloping them in their wall or by isolating them by cellular cleavage. The indications for a surgical intervention should be carefully estimated in each case and the operation must be carried out with great care. All blind extraction procedures are prohibited. Generally the cardiac muscle is extremely adherent to the shell fragments. It must be separated with care and patience, fiber by fiber. Not only is it necessary to have a survey over the entire operative field but also it must be possible to enlarge the opening without delay. Every resection of rib or costal cartilage gives mediocre late results and leaves a weak or deformed area in the wall. Only those procedures should be used which permit a temporary removal of the ribs by section of their cartilages and of their intercostal spaces. A rigorously exact reparation of the wall must terminate the operation. The immediate surgical results are good and they persist in the course of years.

Xenopus Pregnancy Test.—Elkan says that the toad pregnancy test was first described by Hogben in 1930. He himself employed this pregnancy test last year 360 times, using 2,291 toads (Xenopus laevis Daudin) for this purpose. The test proper starts with the collection of urine. The patient is urged to limit the fluid intake as much as possible on the day before the specimen is collected so that the specific gravity of the urine will be high enough. The urine that is eliminated on the day following the restricted fluid intake has a specific gravity of from 1.020 to 1.030, and from 100 to 200 cc. of this urine is sent to the laboratory. It is more difficult to proceed with the test on urines with low specific gravity. Another factor is that the patient must not take any drugs on the day preceding the test. For injection into the dorsal lymph sac of the toads it is possible to use either 2 cc. of untreated urine or 1 cc. of extract, which is prepared according to Zondek's method of precipitation. After the injection the toads are placed in special jars, where they rest on perforated platforms so that they cannot eat their own spawn. For several hours the jars are kept at a temperature of 24 C. The most rapid positive result which the author observed was that oviposition took place four hours and fifty minutes after the injection. The usual time is from six to eight hours. Unfortunately the effect of the same urine on a series of six toads is not always uniform. However, the exactness of the xenopus pregnancy test does not seem to differ from that of the Aschheim-Zondek and Friedman tests. It permits the diagnosis of pregnancy in the early stages with less delay than do other biologic tests. The animals do not have to be killed to obtain the results; they can be used over again. The method is not more expensive than are other biologic pregnancy tests, and the technic is simple and free from error.

Blood and Bone Marrow in Brucella Infection.—Schmid says that the diagnosis of Brucella abortus infection is based on the positive outcome of bacteriologic and serologic methods, namely (1) the demonstration of Brucella abortus in the blood culture or animal tests, (2) the demonstration of agglutinins in the serum and (3) the complement fixation test. In this paper the author gives especial attention to the morphologic aspects of the blood, pointing out that the blood picture in Brucella abortus infection resembles most that of abdominal typhoid. To be sure, this applies only to the leukopoiesis, for the erythrocytes are influenced only slightly or not at all, except that occasionally a mild, secondary anemia is observed. The leukocyte values may decrease to 2,500. Most frequently their number is between 3,000 and 6,000. Mononucleosis exists regularly and the lymphocytes and monocytes show a relative increase, but monocytosis is not as frequent as is lymphocytosis. Among the relatively reduced neutrophils, a deviation to the left is often noticeable and staff-nuclear cells appear. The eosinophils may disappear completely, but they are generally present in reduced numbers. As in typhoid, the leukopenia becomes more pronounced up to a certain point in the course of the disease; but, as recovery approaches, the blood picture becomes normalized. The monocytes behave differently than in typhoid, and the presence of neutrophils militates against typhoid and for Brucella abortus infection. With the exception of the cases that are complicated by hemorrhagic diathesis, the blood platelets remain unchanged. The sternal marrow shows chiefly a myelocytic and a promyelocytic composition, at least in the cases without complications. The author regards this medullary picture as indicative of a mild disturbance in maturation. The medullary changes are of no diagnostic significance. If complications arise in Brucella abortus infection, the blood picture shows a varying behavior. Since little is known regarding the bone marrow in complicated cases, the author gives a detailed report of such a case. The patient had a cutaneous infection with Brucella abortus. At first the course was typical, but then a complication arose in the form of a hemorrhagic diathesis on the basis of a thrombopenia and with hemorrhages in the mucous membranes, necroses, generalized purpura, hematuria and cerebellar hemorrhages. No sternal puncture was made while the patient was alive, on account of the danger of hemorrhage. However, the necropsy revealed periostitis, chronic osteomyelitis with fibrosis, nodules of Brucella abortus infection in miliary dissemination, hemorrhages and atrophy of the substantia spongiosa. Liver and spleen likewise contained nodules of Brucella abortus infection in miliary dissemination. The author thinks that such a characteristic histologic picture is new in Brucella abortus infection. Some of the medullary aspects approach those of panmyelopathy. However, further medullary studies will be necessary to gain a better insight into these problems.

*Ocular Tuberculosis and Benign Lymphogranulomatosis (Boeck's Sacroid, Multiple Benign Miliary Lupoid). F. W. Meyer.—p. 76.

Ocular Tuberculosis and Benign Lymphogranulomatosis (Boeck's Sarcoid).—Meyer shows that the ocular disease which develops in the course of benign lymphogranulomatosis (Schaumann's term for Boeck's sarcoid) or which in some cases exists long before the benign lymphogranulomatosis appears is of tuberculous etiology. The tuberculous character

is indicated by the clinical picture, by the course of the disease and finally by the tendency to the development of secondary phthisis in various organs in the course of benign lymphogranulomatosis. The following aspects are characteristic for the completely developed symptomatology of Schaumann's benign lymphogranulomatosis: peculiar cutaneous efflorescences, osseous changes that are designated as osteitis tuberculosa multiplex cystica (Jüngling), a simultaneous involvement of groups of lymph nodes and peculiar roentgenologic changes in the lungs with enlargement of the mediastinal lymph nodes. In a number of cases ocular disorders develop which exhibit the typical aspects of an ocular tuberculosis. Most likely they represent true tuberculosis of the eye. If the process is completely developed, the tuberculin reaction is usually negative. In the frequent concurrence of benign lymphogranulomatosis and true tuberculosis, the outcome of the tuberculin reaction seems to be determined by the predominance of the one or the other disease. The importance of the roentgenologic aspects of the pulmonary changes is disputed. At any rate, it seems inadvisable to base the diagnosis of benign lymphogranulomatosis only on the roentgenologic changes and perhaps on the negativity of the tuberculin reaction. The outcome of the tuberculin reaction has no corroborative power, since the negative outcome can be observed also in tuberculous processes of other organs and in pulmonary tuberculosis. The peculiarity of the pulmonary aspects does not permit the classification of such cases into a special group, particularly if there exist no changes in other organs. Only microscopic observations permit the definite diagnosis of Schaumann's benign lymphogranulomatosis. Ocular tuberculosis is not an essential aspect of benign lymphogranulomatosis but it frequently accompanies the process; to be sure, it does so not more frequently than does tuberculosis of other organs. Benign lymphogranulomatosis eventually may be an atypical tuberculosis; the term does not indicate the etiology of the peculiar disease.

Permeability for Sulfanilamides of Blood-Cerebrospinal Barrier.—Vonkennel and Schmidt studied the sulfanilamide content of the blood and its passage into the cerebrospinal fluid after oral and parenteral administration. In this paper they give their attention to the permeability of an intact blood-cerebrospinal barrier for sulfanilamides. After the oral or parenteral administration of various sulfanilamides they examined the blood and the cerebrospinal fluid at hourly intervals for a period of five hours. Summarizing their observations, they stress the following points: 1. Soluble prontosil could not be detected in the cerebrospinal fluid. 2. Solution of sodium sulfanilate was found to pass into the cerebrospinal fluid only in the smallest quantities. The salt effect and the hydration capacity are suggested as explanation for this. 3. The para-amino-benzene-sulfonamide (prontosil album) showed an excellent penetration into the cerebrospinal fluid. 4. The dimethyl-disulfanilamide showed practically no permeation capacity, under the conditions employed by the authors. They think that this is due to the slight concentration in the blood and to the molecular volume of the substance. 5. The para-amino-benzene-sulfonacetylamide (albucid) and a carbohydrate compound of sulfanilamide showed the same qualitative behavior as does the pure sulfanilamide.

Coagulation Reaction in Cerebrospinal Fluid in Diagnosis of Syphilis.—Carlinfanti discusses the theoretical foundations and describes the technic of a method which permits the demonstration of syphilitic antibodies and their quantitative examination in small quantities of cerebrospinal fluid and with the aid of inexpensive reagents. It is a modification of a coagulation reaction which was described in 1914 by Hirschfeld and Klinger. It has been employed on 418 specimens of cerebrospinal fluid and the impression has been gained that in view of its sensitivity and because it differs in nature from other reactions it could render good service as an accompanying test to the Wassermann reaction and to the flocculation reactions.

Blood Transfusion in Carbon Monoxide Poisoning.—Koch states that the chief effect of carbon monoxide poisoning and the factor that threatens the life of the patient is the anoxemia, resulting from the formation of carboxyhemoglobin. After discussing measures that have been recommended to counteract this anoxemia, such as inhalation of oxygen or of oxygen and carbon dioxide and the administration of methylene blue, he points out that hemoglobin, which is introduced by means of blood transfusion, will act at once as an oxygen vehicle. Patients who have the signs of severest intoxication, that is, those in whom the reflexes and reactions have been abolished, in whom respiration and circulation are greatly impaired and who do not respond to strong stimulants, many have such a small amount of oxyhemoglobin that inhalation of oxygen, circulatory stimuli and venesection will not prevent death. The author demonstrates, on the basis of case histories, that in such cases blood transfusion after a previous venesection may save the patient's life, because the large quantity of normal hemoglobin introduced in this manner will provide the lacking oxygen more rapidly than will other methods. It is advisable to precede the transfusion by venesection. This procedure removes carboxyhemoglobin from the circulation because the blood in the depots, which is forced into the circulation following venesection, does not absorb the carbon monoxide as rapidly as does the circulating blood. Moreover, the loss of blood stimulates the emergence of new erythrocytes from the bone marrow. If in severe cases of carbon monoxide poisoning venesection and blood transfusion have provided the organism with sufficient oxygen to avert death, the further treatment with oxygen and circulatory stimulants has better prospects of success. The author describes the clinical histories of two patients with severe carbon monoxide poisoning who probably would not have survived without the repeated blood transfusions.

*Prognosis of Arborization Block. F. Kienle.—p. 168.
Danger of Pure Sunstroke, Without Overheating in High Mountains. K. Leonhard.—p. 174.

Prognosis of Arborization Block.—Kienle maintains that the diagnosis of arborization block can be based only on the electrocardiogram. After citing the electrocardiographic characteristics which Weber designates as the basis of the diagnosis of the arborization block, he says that it was generally believed that extensive destruction of or severe damage to the fine terminal fibers of the specific connecting system was the cause of these severe electrocardiographic changes. However, some investigators showed that extensive myocardial changes are the cause of the arborization block and this was proved by the detection of severe organic changes in the myocardium. On the other hand there were investigators who maintained that there is also a "functional" arborization block and it was actually proved that an arborization block was caused by coronary insufficiency and disappeared after treatment with theophylline with ethylene diamine. Here the deficient blood supply had apparently caused "fatigue" but not organic damage in the conduction system. The author further shows that many electrocardiographic curves which have been designated as indicating arbori-

zation block were really branch block curves because the narrowly circumscribed electrocardiographic characteristics of arborization block were not strictly adhered to. The prognostic evaluations based on such records are therefore erroneous. For this reason he investigated the prognosis of arborization block in twenty-five patients who were observed at his clinic and who remained under observation until death. In this material the prognosis of arborization block proved much more unfavorable than was indicated in earlier reports. All of the twenty-five cases terminated in death in the course of one year. The average survival was three and one half months. The mortality curve shows a steep downward trend during the first two months and this is ascribed to the rapid fatal termination of the cases of arborization block, which are caused by infarct. A case is described in which multiple infarcts produced the electrocardiographic aspects of an arborization block, whereas the typical signs of infarct were absent from the electrocardiogram.

Spontaneous Remissions of Schizophrenic Psychoses.—Langfeldt deplores that many investigators of the shock therapy of schizophrenia overlook the fact that their statistical reports are of limited value as long as they fail to state what forms of schizophrenia were treated. He shows that the psychoses which are designated as schizophrenia can be divided into two main groups: (1) the typical schizophrenias, that is those cases which in Kraepelin's terminology are designated as dementia praecox and (2) the so-called schizophrenias, the "schizophreniform psychoses." This second group includes chiefly persons with some manic-depressive aspects and persons with psychopathic tendencies (paranoid, hysterical, asthenic cyclothymic schizoid and others). The typical and the atypical schizophrenias differ greatly in their prognosis. The atypical schizophrenias are nearly all spontaneously cured and, except for a few cases with an intermittent course, the cure is permanent. Shock therapy shortens the duration of these atypical cases. However, it cannot be definitely said as yet whether this is a permanent advantage. Among the schizophreniform conditions that have an acute onset there are also cases that show the typical schizophrenic symptomatology. If these cases are not treated they have an unfavorable prognosis. However, it will require further investigations to determine whether these cases are amenable to shock therapy. The author says that there is an increase in reports which show that the atypical schizophrenias are the ones that react favorably to shock therapy with insulin or metrazol. He emphasizes that all reports on shock therapy of schizophrenia should give attention to the differentiation between typical and atypical cases of schizophrenia.

Treatment of Compound Fractures of the Cranial Vault. G. Ya. Iosset.—p. 680.

Magnesium Sulfate Blood Transfusion in Experimental Shock.—Abramson states that 100 blood transfusions performed in his clinic with magnesium sulfate as a preservative demonstrated the usefulness of this method. In order to test its effect in traumatic shock the author performed animal experiments in which profound shock was induced in anesthetized cats by repeated evisceration and traction on the mesentery. It was found that bleeding the animal one half hour or forty-eight hours before the experiment rendered it more liable to shock. The latter was of such degree that the animals could no longer be saved by intravenous saline transfusion. With the use of magnesium-blood transfusion the author succeeded in saving eight of ten animals. The author concludes that the effect of magnesium sulfate-blood in shock is not inferior to that of citrated or whole blood.

Umbilical Cord as Bone Suture Material.—Shkolnikov describes a method of preparing human umbilical cord to be used as bone suture material. After the blood is expressed from the cord by pressure and rinsing in water, it is dried, shaped and stretched. The dried cord is kept for one month in a solution containing pure iodine 10 parts, potassium iodide 10, alcohol 1,000 and glycerin 80. The solution is changed twice in the course of the month. The cord thus treated proved sterile after multiple culturing. Its tensile power amounted to from 20 to 80 Kg. The author demonstrated in animal experiments that this suture material is absorbed slowly, that is in from two to six months. Roentgenograms and microscopic sections demonstrated a stimulating effect on the various bony elements, in particular the periosteum. The suture was applied in twelve clinical cases, in four of which there were pseudarthroses, in three compound fractures and in five simple fractures. The suture held the bony fragments satisfactorily. There was no infection. The author concludes that this biologic homoplastic material is well suited for bone suture because of its tensile strength, resistance to infection, slow absorption and osteogenic effect.

*Leptospirosis of Dogs in Antwerp. N. van der Walle.—p. 740.
Intestinal Myiasis Caused by Larvae of Sarcophaga Haemorrhoidalis in Child. L. S. Wildervanck.—p. 756.

Leptospirosis in Dogs.—Van der Walle examined 100 dogs of the municipal enclosure for stray animals at Antwerp for leptospirosis. He was able to demonstrate the presence of antibodies to leptospiras in the blood of forty-four of these animals. The number of cases in which Leptospira canicola was more strongly lysed than Leptospira icterogenes was about twice as great as the number in which the other reaction was more prominent. The percentage of infection increased with the age of the dogs. On the whole, a larger number of positive reactions was detected in male than in female dogs. Leptospira canicola was cultivated from the kidneys of one of the apparently healthy dogs. This leptospira appeared only slightly pathogenic for guinea pigs; jaundice was noticeable only after the second passage. Two young dogs which had been intravenously injected with this culture had only a slight temporary conjunctivitis. One of these animals was killed twenty days after the infection; the Levaditi stain showed numerous leptospiras in the kidneys, but exclusively in the tubules.

Hemophilia with Spontaneous Hemorrhage in Iliopsoas Muscle Followed by Injury to Femoral Nerve: Case. A. Tallroth.—p. 1.
*Posttraumatic Disturbances in Region of Appendix, So-Called Traumatic Appendicitis. S. Grettve.—p. 11.
Neurogenic Factor in Strangulation Ileus. H. Wahren.—p. 57.
*Trauma and Leukemia. T. Olovson.—p. 63.
Surgical Treatment of Split Fractures at Proximal End of Tibia. E. Landelius.—p. 90.

Posttraumatic Disturbances of Appendix.—Grettve asserts that the significance of trauma as an etiologic factor in posttraumatic disturbances of the appendix has been overrated. If a blunt force hits the lower right part of the

abdomen directly and with great violence, it may result in rare cases in real damage to the appendix. Minor injuries probably heal spontaneously, but those of a major kind may be complicated by inflammatory processes necessitating operative intervention. If operation is not unduly postponed, it should be possible to ascertain whether the condition is the direct result of injury. On the other hand, it is questionable whether such cases should be regarded as true appendicitis even if the damaged appendicular wall has been overtaken by necrosis and is the seat of secondary inflammatory processes. No external violence is likely to lead to typical appendicitis in a previously healthy and normally functioning organ. On the other hand the possibility exists, at any rate theoretically, that a direct violence to the appendicular region may become the exciting factor in the production of appendicitis in an organ which is the seat of old pathologic changes and which, as a result of impeded emptying, is already threatened by a spontaneous attack. In practice it is probably never possible to exclude with certainty that the appendix before the accident had been the seat of a quiescent or developing inflammatory process which till then had produced no manifest symptoms. Direct violence to the abdomen farther away from the appendicular region or a sudden reflex contraction of the abdominal muscles as a result of the accident cannot produce either damage to the appendix or appendicitis. In some cases prevailing conditions may justify the assumption that appendicitis had been present at the time of the accident. It seems impossible, however, to appraise the true significance of a trauma in a patient with a previously obscure appendicitis. The appendicitis may have begun at approximately the same time at which the patient sustained the accident. On the other hand the violence may have aggravated the inflammatory process, but it hardly will be possible to state to what extent the duration and final outcome of the disease were influenced by the trauma.

Trauma and Leukemia.—*Olovson* describes two cases of myeloid leukemia which occurred in connection with traumas. The leukemia developed after fracture in one and after contusion in the other. Reviewing the literature, the author detected sixty-seven similar cases. In forty of the sixty-nine reported cases the trauma consisted in contusion of the abdomen (splenic region), in twenty-one cases other regions were affected; in eight cases the accident had caused fracture of some bone. The possibility of trauma as a cause of leukemia is being discussed in the light of the present day theories as to how leukemia arises. Some causal connection may quite well exist; the trauma may constitute the exciting factor in a person predisposed to leukemia. Yet it would seem that trauma can play only a small part, as traumas occur frequently but traumatic leukemia is a rare condition.

*Histologic Investigations on Pylorus Gland Organ in Pernicious Anemia. E. Meulengracht.—p. 11.
*Early Diagnosis of Pleural Empyema. M. Olesen and U. Hansen.—p. 19.

Pylorus Gland in Pernicious Anemia.—Meulengracht's examination of the stomach and duodenum from eight patients with clinically and anatomically diagnosed pernicious anemia revealed pronounced changes in the fundus, with atrophy of the glands and disappearance of the special glandular elements. The changes were less definite in the pylorus and the pyloric glands seemed to be relatively well preserved. In the Brunner glands no changes could be demonstrated microscopically. The author discusses the possibilities for reconciling these results with the present conception of the pathogenesis of pernicious anemia. He suggests as the most probable explanation, wholly or in part, a failure of the interaction between the intrinsic and extrinsic factors which originate the third principle, or liver factor, a process which must be ascribed to the intestine, especially the small intestine.

Early Diagnosis of Pleural Empyema.—Olesen and Hansen describe a procedure for recognizing an empyema in its earlier phase, while the pleural exudate is still serous or turbid. The cells from the exudate are stained by Olesen's supravital staining method. Living leukocytes absorb the neutral red in their granules, while dead leukocytes cannot be stained in the weak solution used. In the exudate from seven cases of pleurisy between 22 and 100 per cent of the leukocytes could not be stained, and in these cases an empyema developed in from two to sixty days. In 101 cases in which all the leukocytes were stained, no empyema occurred.

Blood Type A_2B with Strongly Developed Agglutinin a_1 and Relatica of This Type to Blood Transfusion. O. Hartmann.—p. 39.
Variations of Content of Vitamin C in Potato. E. Mathiesen.—p. 42.

Congenital Choledochus Cyst.—Bull states that there are now about 100 known cases of this disorder. Only five cases have been recorded in patients over 41. His patient, a woman aged 42, had abdominal pain, probably due to the biliary disturbance, during childhood and a symptom free period between the ages of 18 and 31 and transient jaundice two years later. On gastrojejunostomy for a callous pyloric ulcer when the patient was 35 no tumor was discovered. Seven years later there was pain in the epigastrium radiating to the spine, with dyspnea; a round, tender, fluctuating tumor, thought to be a retroperitoneal cyst originating from the pancreas, filled the epigastrium. After puncture and removal of 2,250 cc. of thick dark fluid idiopathic dilatation of the common bile duct was diagnosed. Cholecystoduodenostomy was done. Grave infection in the cyst followed and 3,000 cc. of fetid fluid was removed on repuncture; hemorrhagic nephritis and hypochloremic uremia developed. Recurring retention necessitated a third puncture and drainage, with removal of 1,500 cc. of fetid pus. Steady improvement set in and on discharge no tumor was palpable. The author says that idiopathic dilatation of the common bile duct predominates in women. The cardinal symptoms are pain, tumor and jaundice. Grave complications may occur; the contents of the cyst may become infected before or after anastomosis between the cyst and the intestine, there may be a marked hemorrhagic diathesis, and in rare cases the cyst may rupture into the abdomen. Correct diagnosis before operation is said to have been made in only five or six cases. The prognosis depends first of all on the patient's condition at the start of surgical treatment. The mortality for the known cases is about 60 per cent. All authors agree that a communication must be established between the bile duct and stomach or intestine, whether primarily or after preliminary drainage; secondary anastomosis must not be long delayed.

Medicinsk Revue

Duodenal Diverticula. S. Quist-Hanssen.—p. 45.
*Phlegmonous Gastritis. K. Schnitler.—p. 51.

Phlegmonous Gastritis.—Schnitler says that in two of his cases of phlegmonous gastritis the onset was acute and death occurred within four days, while in another, with pain in the epigastrium for several days before admission, the course was more protracted. In the latter, certain reparative changes appeared microscopically in the form of a fairly active formation of connective tissue and fibroblasts. The infection was due to streptococci, either in pure culture or together with staphylococci. In the one case there was a chronic gastritis from misuse of alcohol and a lesion from a bone splinter which had penetrated into the gastric submucosa. In the others, erosions and ulcerations in the gastric mucous membrane are regarded as the port of entry. In phlegmonous gastritis an acute inflammation is present in the submucosa, partly with the picture of a diffuse phlegmon, partly more localized abscesses, or both. The inflammation may progress and occupy practically the whole stomach or be more limited. In the localized cases the seat of the process is usually the pylorus or its immediate vicinity. Diagnosis is not generally made until operation or necropsy. Prognosis is grave. Treatment of the acute cases is surgical. In the localized cases recovery has followed resection of the stomach. In the diffuse form treatment can be only palliative.

NICOTINIC ACID IN THE TREATMENT OF ATYPICAL PSYCHOTIC STATES

ASSOCIATED WITH MALNUTRITION

H. M. CLECKLEY, M.D.

V. P. SYDENSTRICKER, M.D.

AND

L. E. GEESLIN, M.D.

AUGUSTA, GA.

There have been reports of excellent results from the treatment of pellagrous psychoses with nicotinic acid;[1] these have dealt with the more familiar mental symptoms occurring in frank or subclinical pellagra of the usual type. The present communication deals with observations made on nineteen individuals all presenting mental symptoms of somewhat similar pattern, none corresponding to the ordinary conception of pellagrous dementia. Hebetude grading into profound stupor was a feature so prominent that frontal lobe tumor was suspected in three patients, lethargic encephalitis in one and chronic subdural hematoma in a third. Delirium was present three times, agitated depression once, and one patient presented the signs of central neuritis. Signs of peripheral neuritis were not discovered, but five patients had marked deafness which disappeared under treatment; it was difficult to determine whether this transient deafness was due to failure of attention or to actual interference with the auditory mechanism.

The complete syndrome of pellagra was absent and no patient had a history of the disease. Glossitis, in the sense of abnormal redness of the tongue, with or without papillary atrophy and ulceration, was present in all but two of the group. Stomatitis occurred only once, dermatitis was not seen, two patients had mild nonspecific vaginitis and one had diarrhea which developed while under observation. The incidence of gastric anacidity was quite irregular; in many instances gastric contents could not be secured. Inadequate nutrition was evident from the history or the observations made in every case. There was no attempt at rigid control of the diet, feeding was a problem always, and the poor condition of the patients often made the use of a pellagra-producing diet unjustifiable. A few profoundly unconscious patients were of necessity maintained on parenterally administered dextrose and sodium chloride solutions during a part of the treatment period.

All patients were subjected to rather comprehensive clinical and laboratory examination, including a neurologic and psychiatric survey. All usual quantitative, chemical and serologic determinations were made on the blood and cerebrospinal fluid. Electrocardiograms were made soon after admission and often repeated. The excretion of ascorbic acid in the urine was followed in a number of instances.

A great majority of the group were elderly and had organic disease, which might have been considered an adequate cause for the mental symptoms. At least eleven had advanced arteriosclerosis complicated in one instance by cerebrospinal syphilis; one patient had clinical and serologic evidence of cerebrospinal syphilis without peripheral vascular disease, and two men were severely and chronically alcoholic. A control group presenting stupor of demonstrable organic origin was made up of patients with frank cerebral vascular accidents, brain tumor and bromide intoxication.

The use of nicotinic acid was at first quite empirical, the coincidence of stupor and glossitis in obviously malnourished patients suggesting the possibility of incomplete or "cerebral" pellagra as a contributing factor to their dilapidation. Usual methods for hydration and support were taken in every case. Three patients (1, 3 and 4) were given thiamin chloride intramuscularly and intrathecally and one patient (17) took adequate amounts of this vitamin by mouth. Nicotinic acid was administered after other forms of treatment failed to produce improvement; except in case 17 it was given intravenously as sodium nicotinate. Sodium nicotinate was prepared by neutralizing a saturated solution of nicotinic acid with sodium bicarbonate, phenolsulfonphthalein being used as the indicator; the solution was then diluted to a standard volume representing 0.5 mg. of nicotinic acid per cubic centimeter, sterilized in pyrex flasks and stored in a refrigerator until used. Dosage varied from 100 to 300 mg. daily, the treatment period from three to ten days. The usual peripheral vasodilatation occurred during injection of the solution, but no untoward reactions were observed.

Response to nicotinic acid was striking in the group under discussion. In four cases (3, 8, 12 and 15) the vitamin seemed to contribute greatly to improvement; in the rest, "cure" was dramatic. In the control group with demonstrable cause for stupor, no improvement was noted after administration of equal or larger amounts. The results of treatment made it evident that these patients presented a form of pellagra evidently common but seldom recognized, even in endemic areas where physicians are alert to the rather protean manifestations of the disease. We are quite certain

From the Departments of Psychiatry and Internal Medicine, University of Georgia School of Medicine and the University Hosptal.

that the therapeutic test with nicotinic acid was life saving in practically all of the group and equally certain that many persons have been allowed to die because of a failure to recognize the cerebral symptoms of pellagra when other evidences of the disease are absent. Jolliffe [2] has recently reported a somewhat similar experience in patients with signs of central neuritis. We are fully in accord with his suggestion that cerebral manifestations may be the first evidence of severe or complete depletion of nicotinic acid.

While each patient in this series presented phenomena of unusual interest and possible importance, for the sake of brevity the important observations are tabulated and summaries of only six typical case histories presented.

Summary of Cases

No. and Name	Race, Sex, Age	Signs	Associated Diseases	Nicotinic Acid	Result*
1 H. J.	W, ♂, 27	Stupor, glossitis	Alcoholism	100 mg. daily 9/10-9/21, 1938	Well
2 G. M.	W, ♂, 49	Stupor, glossitis	Alcoholism, arteriosclerosis	100 mg. daily 9/26-9/28, 1938	Well
3 M. B.	W, ♀, 42	Stupor, glossitis?	Hysteria	100 mg. daily 9/13-9/22, 1938	Improved (stupor well)
4 A. M.	W, ♀, 57	Stupor, glossitis	Severe macrocytic anemia	100 mg. daily 9/30-10/3, 1938	Well
5 L. J.	W, ♂, 78	Stupor, glossitis†	Arteriosclerosis	100 mg. daily 10/11-10/16, 1938	Well
6 L. W.	C, ♀, 62	Stupor, glossitis	Arteriosclerosis, severe	100 mg. daily 10/9-10/12, 1938	Well
7 H. H.	W, ♂, 54	Stupor, glossitis	Arteriosclerosis, severe	100 mg. daily 10/19-10/26, 1938	Well
8 B. S.	W, ♂, 56	Stupor, glossitis	Arteriosclerosis	125 mg. daily 10/22-10/27, 1938	Improved
9 D. W.	W, ♀, 54	Stupor, glossitis	Arteriosclerosis, syphilis	150 mg. daily 10/17-10/21, 1938	Well
10 M. T.	C, ♀, 24	Stupor, glossitis	.....	100 mg. daily 11/2-11/4, 1938	Well
11 B. R.	W, ♀, 48	Stupor, glossitis,† vaginitis	.....	150 mg. daily 11/4-11/8, 100 mg. 11/9-11/11, 1938	Well
12 S. B.	W, ♀, 54	Stupor, glossitis	Involutional psychosis	150 mg. daily 11/5-11/8, 1938	Improved
13 C. J.	W, ♀, 56	Stupor, glossitis	Abscess of thigh	150 mg. 11/25, 300 mg. 11/26, 150 mg. 11/27, 1938	Well
14 M. L.	C, ♂, 48	Lethargy	Arteriosclerosis, syphilis	200 mg. daily 11/19-11/22, 1938	Well
15 S. H.	W, ♀, 75	Stupor, glossitis	Arteriosclerosis	100 mg. daily 1/2-1/9, 1939	Improved
16 D. B.	W, ♀, 38	Stupor, glossitis†	Syphilis	300 mg. daily 1/4-1/6, 1939	Well
17 R. W.	W, ♂, 78	Stupor, glossitis	Arteriosclerosis, cancer	200 mg. daily by mouth, 12/26, 1938-1/4, 1939	Well
18 V. R.	W, ♂, 58	Stupor	Arteriosclerosis	300 mg. daily 1/13-1/15, 1939	Well
19 J. D.	W, ♂, 54	Stupor, glossitis†	Arteriosclerosis, syphilis	300 mg. daily 1/14-1/17, 1939	Well

* "Well" indicates that stupor and glossitis were entirely cured, not that associated chronic diseases were influenced. "Improved" indicates that stupor and glossitis were cured but organic or functional mental changes of nonpellagrous origin persisted.
† Typical pellagrous glossitis.

CASE HISTORIES

CASE 1.—H. J., a white man aged 27, was admitted to the University Hospital Aug. 27, 1938, from the city jail, where he had been taken in an alcoholic stupor. There was a history of severe chronic alcoholism. On admission the patient was well developed and well nourished, stuporous and with no evidence of paralysis. Ophthalmoscopic examination showed normal fundi. The tongue was red, dry and rough. General physical examination was not significant. Neurologic examination showed absence of knee and ankle jerks and no abnormal reflexes were present; there was definite response to painful stimuli. All routine laboratory examinations were of no significance. The cerebrospinal fluid was under 90 mm. of water pressure, the Queckenstedt test was negative, the cell count and protein content were normal and reactions with colloid gold and mastic suspensions were negative. Intubation was done and a liquid high vitamin diet was instituted. Thiamin chloride was given intrathecally, 20 mg. August 27, August 31 and September 4. The usual treatment for cerebral edema was carried out but no improvement resulted. For fourteen days the man lay in deep stupor; September 10, nicotinic acid was given, 100 mg. intravenously as sodium nicotinate; during the afternoon some four hours after treatment the man regained consciousness and spoke rationally. Treatment was continued for ten days; on the second day solid food was requested and on the fourth the patient was up and walked about the ward. Neurologic examination on the day when consciousness returned showed no evidence of peripheral neuritis. September 12 the fasting contents of the stomach showed 38 degrees of free hydrochloric acid and 47 degrees of total acidity. The man was discharged well September 26.

CASE 4.—A. M., a white woman aged 57, was admitted to the University Hospital Sept. 20, 1938. A history obtained from the relatives told of progressive difficulty in walking and almost constant headache for the past two years; during the past three weeks the patient had become almost completely ataxic and entirely lethargic. She was well nourished and well developed, apparently stuporous but could be aroused by drastic stimulation. The temperature was 98, the pulse 88, the respiratory rate 22 and the blood pressure 120 systolic, 80 diastolic. The skin was dry, a lemon yellow and free from blemishes. The tongue was liver colored with complete atrophy of the papillae. There were systolic murmurs at the mitral and aortic areas of the moderately enlarged heart. The peripheral arteries were large, firm and tortuous. The liver and spleen were not felt. The uterus and adnexa were senile. Neurologic examination after some difficulty showed a broad-based gait with staggering while supported. Romberg's sign was present and the finger to finger and heel to shin tests showed marked ataxia. Knee jerks were hyperactive but no abnormal reflexes were present. The pupils were irregular and responded quite sluggishly to light. After mydriasis, only pallor of the retina and retinal arteriosclerosis were evident. On psychiatric examination the patient was stuporous and entirely unable to cooperate. The blood contained 11 Gm. of hemoglobin per hundred cubic centimeters, 2,500,000 red blood cells and 7,800 white blood cells per cubic millimeter, with 160,000 platelets per cubic millimeter and 0.5 per cent reticulocytes. The color index was 1.2, the volume index, 1.2. The gastric contents after histamine September 22 showed 0 free hydrochloric acid and 12 degrees of total acidity. The cerebrospinal fluid was normal. The urine and stools contained an excess of urobilin. Blood smears showed anisocytosis, poikilocytosis and macrocytosis. Nucleated erythrocytes were not seen, platelets were abundant and no abnormal leukocytes were noted.

The diagnosis of addisonian anemia was made and concentrated liver extract-Lilly was given, 15 cc. intramuscularly as a depot dose September 23, following by 3 cc. daily for five days. Thiamin chloride 10 mg. was given intrathecally September 22 and 10 mg. intramuscularly was administered from September 23 to October 3; 400 cc. of blood was transfused September 24. No reticulocyte response followed the use of liver extract; daily counts varied between 0.3 and 0.6 per cent, nor was there any clinical improvement.

September 30 nicotinic acid (as sodium nicotinate) 100 mg. was given intravenously and continued until October 4. On October 1 the patient was conscious and cooperative and ate ravenously of the regular ward diet. On the following day she was alert and entirely rational. October 5, oral administration of nicotinic acid was substituted for intravenous treatment and 300 mg. was given each day in doses of 50 mg. every two hours from 8 a. m. to 6 p. m. Ferrous gluconate was prescribed, 5 grains (0.32 Gm.) three times a day. Clinical improvement was rapid. October 14 the patient was able to be up and around the ward. By October 18 all neurologic signs had disappeared; the patient was rational and

2. Jolliffe, N. H.: Effects of Vitamins on Mental and Emotional Processes, read before the Association for Research in Nervous and Mental Diseases, New York, Dec. 27, 1938.

in good spirits. The blood contained 12.5 Gm. of hemoglobin per hundred cubic centimeters, 4,200,000 red blood cells and 9,500 white blood cells per cubic millimeter. Volume and color indexes were 1. No reticulocytosis was observed; the maximum count was 0.8 per cent. The patient was discharged October 19 apparently well.

CASE 5.—L. J., a white man aged 78, was admitted to the University Hospital Sept. 30, 1938. A history obtained from the relatives told of increasing weakness and lethargy over a period of several weeks; eight days before admission the patient became bedfast and stuporous. He was fairly well nourished, stuporous and mildly delirious. The temperature was 99.2 F., the pulse 80, the respiratory rate 20 and the blood pressure 186 systolic, 110 diastolic. The skin was dry and wrinkled, the retinal arteries were sclerotic and the tongue was dry, bright red and atrophic. There was evidence of pulmonary congestion; the heart was moderately enlarged. There was advanced peripheral arteriosclerosis. Laboratory examinations showed moderate hypochromic anemia, normal renal function and electrocardiographic evidence of coronary sclerosis. The gastric contents could not be obtained. A liquid high vitamin diet, concentrated solutions of dextrose given intravenously and full doses of digitalis had no effect on the patient's condition. October 11 nicotinic acid was given, 100 mg. intravenously as sodium nicotinate, and repeated daily until October 16. On the second day of treatment the patient was alert and attentive and the tongue was pink and showed many small papillae. By October 14 the sensorium was entirely clear and the tongue normal. The patient was dismissed well October 19 and remained apparently well until Jan. 20, 1939, when he died suddenly from massive cerebral hemorrhage.

CASE 10.—M. T., a Negro woman aged 24, admitted to the University Hospital Oct. 27, 1938, had been seen many times in the outpatient department during the previous eight months complaining of headache and general malaise. In March 1938 she showed marked lethargy and March 31 a lumbar puncture yielded normal cerebrospinal fluid. During October consciousness became so clouded that she could not keep her eyes open or answer questions during an interview. There were no signs of an active psychosis.

On admission she was well developed and fairly well nourished, uncooperative and apparently stuporous. The temperature was 99 F., the pulse 80, the respiratory rate 18 and the blood pressure 132 systolic, 96 diastolic. The skin was normal. The left pupil was slightly larger than the right; both reacted normally to light and in accommodation. Ophthalmoscopic examination showed normal fundi. The tongue was red with smooth tip and edges; there was no stomatitis. No abnormalities were discovered on examination of the thorax, abdomen and genitalia. The knee and ankle jerks seemed slightly increased on the right. The patient lay with her eyes closed, entirely inert; she could be roused but consciousness was much clouded and she did not ever speak spontaneously. On being persistently roused she seemed oriented but failed to answer questions adequately, and it was impossible to hold her attention. Delusions and hallucinations seemed to be absent. The blood showed moderate hypochromic anemia; chemical determinations of the blood were negative and the Wassermann and Kahn reactions were negative. The urine showed nothing unusual. The gastric contents after administration of histamine contained 0 free hydrochloric acid and 14 degrees of total acidity. The cerebrospinal fluid was again normal in all respects. An electrocardiogram showed evidence of slight myocardial damage.

Because of persistent hebetude, frontal lobe tumor was strongly suspected; the possibility of chronic subdural hematoma was also considered. No nutritional history was obtainable but it was decided to try the effect of nicotinic acid, since there was mild glossitis and achlorhydria. Nicotinic acid 100 mg. was given intravenously as sodium nicotinate November 2, 3 and 4. About five hours after administration of the first dose there was a very definite change; the patient was fairly alert and answered questions quite satisfactorily. The following day she was more normal than she had been since she came under observation, responding promptly and rationally and showing keen interest in her surroundings. She remained clear mentally throughout the remainder of her stay in the hospital, talking freely, observant of all details and showing active and appropriate affective reactions. An encephalogram November 6 showed slight atrophy of both frontal lobes. The gastric contents obtained after administration of histamine November 10 contained 18 degrees of free hydrochloric acid and 35 degrees of total acidity. She was dismissed, apparently well, November 14.

CASE 11.—B. R., a white woman aged 46, was admitted to the University Hospital Nov. 2, 1938, with a tentative diagnosis of carcinoma of the uterus. There was a history of a foul vaginal discharge for some months, with progressive loss of appetite. During ten days preceding admission she had become progressively more weak and irrational, then stuporous and incontinent. She was small, emaciated, immobile and unconscious. The temperature was 100.2 F., the pulse rate 82, the respiratory rate 22 and the blood pressure 100 systolic, 30 diastolic. The skin was loose and dry; there was no dermatitis. The pupils were large and equal and they reacted to light; ophthalmoscopic examination showed normal fundi. The patient was edentulous, the tongue was red and smooth and there was no stomatitis. The lungs, heart and abdomen seemed normal. There was mild vaginitis with a profuse purulent discharge; the uterus and adnexa were normal. All tendon reflexes were much exaggerated with sustained ankle and patellar clonus and Chaddock's sign. The rectal and vesical sphincters were incontinent. There was no response to questions; strong painful stimuli were evidently felt but failed to rouse the patient. There were frequent sucking movements of the lips and cheeks and from time to time spontaneous grasping movements of the hands. There was slight hypochromic anemia; chemical and serologic examinations of the blood were negative. The urine showed moderate amounts of acetone. The gastric contents after administration of histamine contained 0 free hydrochloric acid and 14 degrees of total acidity. The cerebrospinal fluid was normal in all respects. X-ray examination of the thorax and of the gastrointestinal tract was negative.

An indwelling tube was installed for the administration of fluids and liquid diet. Psychiatric and neurosurgical consultants suggested central neuritis and frontal or hypothalamic tumor as possible explanations of the patient's condition. Because of mild glossitis and vaginitis with stupor, it was decided to give nicotinic acid. Amounts of sodium nicotinate solution equivalent to 150 mg. of nicotinic acid were given intravenously November 4 to 8 and then reduced to amounts representing 100 mg. until November 12. Some six hours after the first dose of sodium nicotinate the patient was definitely more responsive and the sensorium, while still clouded, was remarkably clearer. On the second day of treatment the patient was fairly cooperative, noticed the examiner, protruded the tongue on request and answered questions; on this day the indwelling tube was removed and a soft diet was taken. Sucking and grasping movements were less frequent and spasticity was less marked. On the following day she was alert and answered questions rationally. The sphincters were under control and primitive motor phenomena had ceased; all reflexes were normal. On this day the tongue was normal and there was no vaginal discharge. Subsequent improvement was rapid and the patient was dismissed, apparently normal, November 23.

CASE 18.—V. R., a white man aged 58, was admitted to the University Hospital Jan. 13, 1939. There was a history of gradually developing weakness and of aching of the feet with stumbling at night; a sensation of thoracic compression and increasing drowsiness had been present for about four months. He was emaciated, inert and entirely inattentive and looked much older than his stated age. The temperature was 98.6 F., the pulse 90, the respiratory rate 18 and the blood pressure 140 systolic, 80 diastolic. The skin was loose and dry and free from eruption. The pupils were irregular and reacted sluggishly to light and in accommodation. The optic disks were abnormally well defined and gray; the retinal arteries were tortuous and irregular. The tongue was rough and coated, with moderately red tip and edges. The lungs and heart were

not remarkable. The abdomen was scaphoid and the walls were soft. Reflexes were sluggish but no abnormal reflexes were found. There was great difficulty in holding the patient's attention when he was roused; the speech was slurred and there was marked apparent impairment of hearing. No sensory disturbances were found; the gait was slightly ataxic. The blood was normal in all respects, as was the urine. The cerebrospinal fluid showed no abnormalities.

Because the patient was lethargic and evidently poorly nourished it was decided to try the effect of nicotinic acid, though none of the usual signs of pellagra were present; 150 mg. was given intravenously on the evening of January 13 and 300 mg. January 14 and 15. On the morning of January 14 the patient was alert and cooperative, attention was readily gained and held and hearing seemed greatly improved. By the following day all mental clouding had disappeared, as had the speech defect and slight incoordination of the legs. He stated that he felt entirely well, and he was dismissed January 16 with no persisting symptoms.

COMMENT

The results obtained with nicotinic acid in this group of patients would seem to leave no doubt that the stupor, which was the presenting sign in every case, was due to specific deficiency of vitamin. No improvement followed the administration of nicotinic acid to patients with bromide intoxication, brain tumor or recent cerebral hemorrhage or thrombosis. It is to be emphasized that stupor was the single phenomenon common to the group. Glossitis was typical of pellagra in not more than four instances; two patients had rough coated tongues and the other thirteen had tongues which were dry and abnormally red but with abundant papillae, a type commonly referred to as "toxic" or "dehydrated." Gastrointestinal symptoms were absent and no patient showed dermatitis of any sort. The high proportion of elderly patients with advanced arteriosclerosis is significant in that such persons are apt to be without means of livelihood and severely undernourished as a result of neglect by relatives or of their own indifference. In our experience such patients have fallen into a high mortality group usually inadequately diagnosed "cerebral arteriosclerosis" or "cerebromalacia," hospitalized as a gesture and perfunctorily treated until death from bronchopneumonia. It is not to be supposed that we suggest that all stuporous conditions of obscure etiology are manifestations of pellagra. We have, however, been impressed by the dramatic improvement obtained in this series of cases and we are convinced that a therapeutic test with nicotinic acid is justifiable in cases of unexplained hebetude or unconsciousness.

Apparent deafness was a striking feature of five of our cases (2, 13, 14, 18 and 19). It was very difficult to evaluate the improvement in hearing which followed treatment with nicotinic acid. Unquestionably the threshold of auditory perception was raised during the period of stupor, but in two cases (13 and 14) there was a progressive increase in auditory acuity after hebetude had disappeared.

SUMMARY AND CONCLUSIONS

Nineteen stuporous patients showed remarkable improvement after treatment with nicotinic acid.

The usual criteria for the clinical diagnosis of pellagra were largely absent; four patients had the pellagrous type of glossitis and two had vaginitis; dermatitis and diarrhea were not present on admission in any case.

A great majority of the group were elderly with advanced arteriosclerosis and presented a clinical picture commonly attributed to arteriosclerotic encephalopathy.

Hebetude grading into profound stupor may be the only sign of severe acute pellagra, and therapeutic trial of nicotinic acid is justifiable as the only method at present available for the accurate diagnosis of such cases.

It is our present conviction that nicotinic acid was life saving in all but one or two of the cases under discussion.

BORDERLINE STATES OF NUTRITIVE FAILURE

JAMES S. McLESTER, M.D.
BIRMINGHAM, ALA.

Nutrition now occupies the center of the stage. Formerly she played only a minor, somewhat unattractive, role and her lines were few, but today she enjoys a leading part and has the spotlight. Still greater brilliance of performance is promised. This advancement began about a quarter of a century ago when man's imagination was fired and his zeal for scientific inquiry kindled by the discovery that certain hitherto unknown substances, later called vitamins, although required only in minute amounts, are absolutely essential to the orderly progress of an animal's life processes. Without these substances the young fail to grow and the older animal sickens. It is of this sickness, in its many forms, that I wish to speak.

Three facts concerning nutritive failure are becoming increasingly obvious: first, that it does not come solely from lack of vitamins but from deficiency of proteins and minerals as well; in certain of the lower animals it comes even from lack of fats; second, that in America it is seldom complete; and third, that it is not, as a rule, the expression of a single nutritive fault. More often it is partial in extent and multiple in nature with a clinical picture that is correspondingly lacking in detail and hazy in outline.

Important too is the growing realization that nutritional failure is not the result solely of failure of supply, for it is frequently encountered in persons whose food supply is fully adequate. True, many of these patients simply do not eat the food offered them but there are others who, even though they consume adequate food of the right kind, suffer nonetheless from nutritive failure. Theirs is not a problem of the choice of food but of its digestion, absorption and utilization.

The first problem of this character was solved when Castle demonstrated that one of the most common of deficiency diseases, pernicious anemia, is due to a defect of the stomach. Then came reports telling of syndromes of similar character resulting from carcinoma of the stomach, gastrectomy, intestinal anastomosis and partial intestinal obstruction. Even rapid emptying of the stomach or long continued diarrhea may so interfere with digestion and absorption as to lead to nutritive failure. Witness the macrocytic anemia of sprue, due directly in all probability to poor absorption of the extrinsic factor of Castle and more remotely to the alterations in muscle tone and mucosal pattern characteristic of this disease.[1] Even nutritive deficiency

---

The DaCosta Foundation Oration, read before the Philadelphia County Medical Society, Philadelphia, March 15, 1939.

1. Mackie, T. T.; Miller, D. K., and Rhoads, C. P.: Sprue: Roentgenologic Changes in the Small Intestine, Am. J. Trop. Med. 15:571-589 (Sept.) 1935.

itself, as Miller and Rhoads [2] have shown for the vitamin B complex, may so impair the integrity of the alimentary tract as to interfere with the absorption of other essential substances and thus lead to additional deficiencies of still other types. The same is true of peptic ulcer and chronic ulcerative colitis, which are sometimes attributed to nutritive failure but which are themselves, in all probability, the cause of the deficiencies noted. Apparently anything which seriously impairs the integrity of the gastrointestinal tract may so interfere with digestion and absorption as to lead to nutritive failure.

Such interference, however, is not limited to structural anomalies. Like difficulties are created by abnormalities of the digestive fluids, as can be seen most often in the deficiency states associated with achlorhydria. Just what role this defect plays it is difficult to say, but it is apparently of significance in a number of disorders other than pernicious anemia, notably pellagra and sprue. Even in the hypochromic anemias it plays a part, for in the absence of free hydrochloric acid from the stomach contents iron is not converted from the ferric to the ferrous state and therefore is not readily available for use. Similar hindrances are imposed by the absence of bile from the intestinal tract, for in this condition carotene, the precursor of vitamin A, and perhaps vitamin D also, fail of absorption and there results a deficiency of these elements.

Still other factors are capable of causing deficiency diseases in the face of an adequate food supply. Vitamin A and iron, for example, are both poorly utilized in the presence of an infection. In the case of the latter this was well illustrated by Whipple [3] when he told of the dog which ceased to build hemoglobin properly from injected iron when a focus of infection developed but which, as soon as the focus was removed, again produced hemoglobin in expected amounts. Additional evidence of this character is seen in the report of Kellogg and Mettier [4] that iron is poorly utilized when, as in peptic ulcer, alkalis are given.

Another potent cause of nutritive deficiency, hitherto unrecognized, is the ease with which the balance between vitamin requirement and energy output is upset, for the former is as a rule dependent on the latter, profoundly so in the case of vitamin B_1. If, for example, as was pointed out by Cowgill [5] and more recently emphasized by Williams and Spies,[6] a person consumes increased quantities of carbohydrate or alcohol; if, because of hyperthyroidism, fever or additional exercise, he increases appreciably his metabolism or, in the case of a woman, if she becomes pregnant, the requirement for vitamin B_1 is greatly increased. If the diet in this respect has hitherto been a borderline one, nutritive deficiency results and characteristic symptoms may develop.

Similar results may follow disturbances of intermediary metabolism, notably those which accompany disorders of the liver. Many substances are stored in the liver and when it is diseased the body may be deprived of reserves of essential nutritive elements on which it is accustomed to rely. If this organ is cirrhotic, for example, not only is the storage of vitamin A interfered with but the conversion of carotene into the vitamin is retarded. In addition, poor utilization of vitamin D [7] and inadequate production of plasma proteins are also experienced. The low levels of ascorbic (cevitamic) acid reported in the blood during rheumatoid arthritis and the assumed increase in requirement are also apparently due to disturbance of intermediary metabolism. It can safely be said, therefore, that the requirement of the body for vitamins and other nutritive essentials is governed by many factors, prominent among which are the condition of the gastrointestinal tract and the functional integrity of the liver.

No discussion of diet today would be complete without some mention of the distinction which is becoming increasingly obvious between minimum and optimum. As applied to nutrition the two words are by no means synonymous. Witness the report of Sherman and Ellis [8] concerning vitamin G and of Batchelder [9] concerning vitamin A showing in each group of experiments that the animal's improvement in vigor and nutritive well-being paralleled closely successive additions of the vitamin to the diet until an amount of this substance was administered which was several times that necessary to prevent evidences of nutritive deficiency. Like experience in the feeding of vitamin B to children was reported by Knott.[10] Since the body is apparently unable to build adequate reserves of this vitamin, she assumed that the highest retention represented the optimum intake and found that this point was reached only when six or seven times the minimum requirement was given. Such studies lead to the conclusion not only that optimum in this relationship is distinct from minimum but that it is to be distinguished even from adequate.

Subclinical states of nutritive failure hold greater interest for the average physician than do the outspoken deficiency diseases, both because they are more frequent and because without creating recognizable illness they often destroy the patient's efficiency, impair his sense of well-being and constitute a potent source of poor health. The recognition of these states, however, is not easy because there is no yardstick by which nutritive status can accurately be measured. The effort is being made to perfect methods of precision which will serve this purpose, but except for the determination of the ascorbic acid of the blood and possibly the capacity of the eye for dark adaptation, none of these are suitable yet for general use. The physician must rely on painstaking clinical observation and a recognition of those conditions under which nutritive deficiency is most apt to occur. The symptoms, which are well represented in a group of patients of whom I shall speak presently, are as a rule rather vague and elusive. Significant symptoms always are sore tongue and tendency toward diarrhea, but when these appear the disease can hardly be classed as subclinical. Careful questioning will often reveal faulty dietary habits,

extreme faddism, substandard conditions of living, a long continued illness or operation perhaps, or some other circumstance which has influenced the state of the patient's nutrition. Recognition is often made more difficult by the multiple nature of the deficiency. Even such a clearcut disease as pernicious anemia is frequently complicated by contributory deficiencies. As was well expressed by Minot,[11] it is often of more practical importance to recognize that the patient has nutritional deficiency than to be able to name exactly what nutritional deficiencies he has.

The physician who attempts to describe nutritional failure should confine himself to the disorders seen within his own area of activity, for climate, soil, food supply, racial customs, economic considerations, are all of profound influence. I can speak, therefore, only of my own observations in the Gulf states, but these, I believe, will permit of a fair amount of generalization. My interest in nutrition was aroused many years ago by experience with a group of patients who are ordinarily shunned by most physicians. These patients, while presenting a great variety of symptoms, have in common easy fatigue, both mental and physical, anemia of varying degree, digestive disorders of every type and of all grades of severity, aches and pains that are not necessarily constant in time or location, a lowered basal metabolic rate perhaps, dryness and other minor disturbances of the skin, and an emotional instability that physicians are accustomed to associate with neurasthenia. But neurasthenia is a poor diagnosis always, and for this group in particular it is a highly unsatisfactory one. It seemed best at that time to make no diagnosis, and for a number of years with a large measure of success these patients were treated without a diagnosis.

Today, after watching the response of the patient of this type to a more liberal diet, I now feel convinced that his troubles are due largely to nutritive deficiency. The vague pains of which he so often complains are not the expression merely of heightened emotionalism; too often they are reminiscent of the symptoms described by Brennan[12] in the latent beriberi seen in the Philippines. The same is true of his easy fatigue, palpitation and insomnia. Likewise, I think it fair to assume that his vague digestive disorders, even though they depend on functional derangement rather than on structural damage, are none the less genuine. When one recalls the description by Cowgill and Gilman[13] of the depression of gastric secretory activity produced by lack of the vitamin B complex, and that of Shimazono[14] of the altered intestinal motility which accompanies the same deficiency, it is not difficult to recognize the true nature of these disabilities.

The patients of whom I speak have been put to bed in the hospital, reassured, given a pat on the back, and forced to eat a liberal, well balanced diet, a type of diet to which, as a rule, they were utterly unaccustomed and against which they sometimes rebelled. In the majority of instances the improvement has been thoroughly satisfactory. The aches and pains have disappeared, foods were eaten that formerly were regarded with great fear, emotional stability has been established, and the patient has not infrequently blossomed out like a rose. He was cured, at least for the time being, but of what he was cured I formerly had many doubts. Now I believe I know. It was not, as was at first thought, the seclusion, the opportunity for quiet contemplation, the reassurance, the atmosphere of encouragement or the pat on the back that accomplished the cure. It was food.

High in the list of such disorders should be placed the so-called prepellagrous state. Since J. B. McLester in his study of the histories of pellagrins seen at the Hillman Hospital in Birmingham made the significant discovery that an appreciable number of these patients had been admitted the previous year under the diagnosis of neurasthenia, we have made an effort toward the early recognition of such cases of subclinical pellagra. Many of the patients recently studied could with some justice be called neurasthenic, but when given nicotinic acid and thiamin, with a diet appropriate for pellagra, they recovered their nervous stability and sense of well-being to a remarkable degree. I believe that with a good history the prepellagrous state can be recognized without great difficulty and further progress of the disease stopped.

Among the discoveries made by Spies and his associates in these pellagra studies two are deserving of mention here. First, abundant confirmation was found of the belief which I expressed a few years ago[14a] that the deficiency responsible for the manifestations of this disease is as a rule multiple in nature. Nicotinic acid will relieve in a graphic manner the psychic and the gastrointestinal symptoms of pellagra, but experience has shown that vitamin B_1 is required for relief of the neuritis. Second, it was demonstrated early in this work that a diet fully adequate to protect against pellagra will not necessarily arrest the disease once it is started; the same nutritive substances are required but in greatly increased amounts. The conclusions drawn from these observations apply, experience has led me to believe, not only to pellagra but also to many other deficiency states, borderline and outspoken.

The minor disorders that appear in the twilight zone of nutritive failure are many and varied. In this group can be placed the normocytic anemia, with a slightly macrocytic tendency, ascribed by Minot[15] to lack of vitamin C and the iron deficiency anemia seen among many young women. This last, although mild, is apparently identical with the chlorosis frequently described forty years ago. In the same category belong the dermatoses of minor extent described by Youmans and Corlette[16] and others and the peculiar dystrophy of the nails reported by White. In the first group improvement was effected by the administration of vitamin A and in the second by vitamins A, B and D. I am not familiar with the beriberi heart described by Weiss and Wilkins,[17] but I believe that other disorders which accompany low grade vitamin B_1 deficiency, difficult of accurate appraisal, are

of relative frequency. Among these should be included many so-called functional digestive disorders with anorexia and loss of gastrointestinal muscle tone, and many forms of neuritis, both single and multiple. Witness the neuritis of pregnancy which Strauss and McDonald[18] successfully treated with abundant diets rich in vitamin B_1, and the neuritis of diabetes mellitus, which Williams and Spies[6] believe is due to vitamin B_1 deficiency.

Other disorders, the nature of which is sometimes difficult of recognition, accompany low grade protein starvation. This deficiency does not always produce effects as outspoken as the nutritive edema and other evidences of faulty diet described by Youmans in the mountains of Tennessee. Less obvious symptoms such as weakness, pallor and the pitting of the ankles and puffiness of the eyelids that follow long continued illnesses may result from lack of protein. In this group should be placed also the toxemias of pregnancy which Strauss[19] has shown to be due to hypoproteinemia, and certain of the hypochromic anemias. A large proportion of the circulating protein is included in the hemoglobin molecule, and without a sufficient supply of this foodstuff hemoglobin is inadequately produced. Evidence of this is seen in the experiments of Weech and his associates,[20] whose dogs, maintained on a diet deficient in protein, experienced a marked fall in red blood cells as well as depletion of circulating proteins. This explains why hypochromic anemia is sometimes so refractory to treatment. Lack of protein is far reaching in its effects.

The relationship of inadequate diet to disease is not always direct. It would take a stretch of the imagination to regard cirrhosis of the liver as a deficiency disorder, yet Connor[21] looks on starvation or partial starvation, plus alcohol, as first among the causes of this disease. He lists the several types of faulty diet which prepare the way and doubts whether the adequately nourished person, even though he uses alcohol to excess, ever develops cirrhosis. Even cataract has been brought into this category. Bourne[22] suggests, since the lens is a growing tissue and since relatively large amounts of essential amino acids are required for the elaboration of its protein, that this structure is in all likelihood susceptible to protein deficiency. A similar influence is attributed to vitamin C, which is normally present in the lens. Since the amount of ascorbic acid is less in the lenses of older animals and least of all in cataractous lenses, and since ascorbic acid is so intimately concerned in the metabolism of this structure, it is thought that its withdrawal will produce degenerative changes. Because of the low ascorbic acid levels reported in the blood of rheumatoid diseases[23] arthritis is also included in this group. Such examples cannot be regarded as final evidence of a directly causative relationship, but they illustrate nonetheless the fact that diseases which apparently are of other origin may develop on a basis of nutritive deficiency.

The chronic undernutrition which leads to the disorders just discussed is far reaching in its effects and sometimes difficult of correction. Witness the experiments of French and Bloomfield,[24] who demonstrated that rats which have lost weight as the result of a defective diet and then have been restored to normal by a stock ration subsequently show more rapid weight loss when again placed on the same defective diet, which is taken to indicate that there has been some real alteration in the status of the animal. This principle is probably applicable to man also, for it is well established that long continued undernutrition will lead to general physical inferiority, small stature, skeletal defects and even intellectual retardation. That nutritive failure during the formative period of life if long continued may result in damage which can never again be completely corrected is evident in the small stature and mental and physical inferiority of children reared in undernourished families.[25] Continued into adult life, such deficiencies may also lead to early decay, as was seen in the experiments of McCollum, who found that mice reared on a diet within the "twilight zone" of good nutrition exhibit relatively early the signs of senility and fail to live out their normal span of life. Other animals show the same tendency; man is probably no exception.

ILLUSTRATIVE CASES

In closing I would like to tell of a few patients who have suffered from the deficiency states I have attempted to describe and then speak briefly of treatment. A patient whose gallbladder had been removed was having a stormy convalescence. She could not be induced to eat, was prostrated far beyond what could reasonably be expected, and was apparently developing a psychosis. In view of her "finicky" appetite and of her history of never having eaten properly since childhood, she was finally given nicotinic acid and daily intramuscular injections of liberal amounts of liver extract. The result was graphic. The psychoneurosis disappeared, she began to eat, and convalescence ensued. The starvation incident to the illness and subsequent operation had simply pushed a borderline deficiency over the border.

Another patient's diagnosis varied from time to time between inadequate personality, constitutional inferiority and neurasthenia. In addition to his numerous bodily complaints he was utterly lacking in stamina. He experienced frequent emotional upsets and could work only a few days at a time; even then he was thoroughly inefficient. Finally, because of the similarity between this young man's complaints and those of many early pellagrins, he was given, in addition to an abundant diet, nicotinic acid. There was immediate improvement. He returned to work and continued to work steadily. Because, no doubt, of damage done to his nervous system many years ago, the original diagnosis of constitutional inferiority still holds good, but since he has taken nicotinic acid his difficulties have largely disappeared.

Vallebona [18] reported a cure in one case but failure in four other cases. Cignolini [12] failed in seven cases to effect recovery. Lezius,[20] in a monograph published in 1936, said that he had observed no healing of abscesses after short wave therapy. One of his patients died of hemorrhage immediately after irradiation and a second two weeks later from extensive new areas of destruction of lung tissue. In a paper on the treatment of gangrene of the lung written from the Heidelberg surgical clinic, Lezius [19] said "We had very poor results *with roentgen* and short wave irradiation of the lung" (Ganz schlechte Erfahrungen machten wir mit Roentgen- und Kurzwellenbestrahlung der Lunge). In ten cases Jacchia and Ghetti [21] failed to obtain a cure, but in four they claimed complete recovery. Vosschulte and Schwarzhoff [22] in a recent paper stated that they had operated in two cases in which short wave therapy had been employed for a long time without any success.

Fig. 1 (case 1, June 21, 1935).—Large shadow involving nearly one half of the entire right lung field (which has a circular outline in the oblique position). No fluid level was visible. Diagnosis: large lung abscess.

We have collected from the literature 129 cases of lung abscess and gangrene treated with short waves by eighteen clinicians, as shown in the accompanying table. Eighty-seven of the patients, or 67 per cent, were reported to be cured.

The following series has been carefully studied. The patients with two exceptions were hospitalized during the course of therapy. This made possible a careful observation of temperature, pulse, physical signs, sputum and blood sedimentation rate. Roentgenograms were made at frequent intervals. Schliephake's original recommendations regarding technic were carefully followed.

Treatments were usually given daily, beginning with an initial one of ten minutes' duration. The duration was gradually increased to thirty or even forty-five minutes. Large glass electrodes 20 cm. in diameter were used. They were usually placed from 4 to 6 cm. from the skin. The wavelengths selected were 4 cm. or 6 cm. A large two vacuum tube machine was used. It has an output of 500 watts when generating a 6 meter length.

During the first treatments increased expectoration was often noticed. In one case treatment was discontinued for three days owing to the presence of blood in the sputum. The treatments did not disturb the patients after they became accustomed to the procedure.

ACUTE LUNG ABSCESS

CASE 1.—*History and Course.*—M. H., a girl aged 10 years, had had a tonsillectomy April 27, 1935, and pain in the right side of the chest June 6. Later fever and cough developed, w foul sputum. On her admission to the Boston Floating Hosp *June 20* there were *dulness and diminished* breath sounds o the right side of the chest. X-ray examination showed evide of a lung abscess (fig. 1). The temperature varied between 1 and 103 F. and the pulse was accelerated. The total amount sputum was from 20 to 80 Gm. daily. July 1 short wave tre ment was begun. Three days later the temperature fell normal. July 6 the physical signs had disappeared. The blo sedimentation rate dropped from 55 mm. in one hour July 1 22 mm. July 16. No further determination was made un December 3, when it was 4 mm. in one hour. July 11 a roen genogram showed clearing of the infiltration, but the cavity w unchanged (fig. 2). During the following month it shrank until measured only 2 cm. by 1 cm. In a roentgenogram made Augu 23 the abscess was no longer visible (fig. 3). There was a goo gain in weight, and the patient seemed to make a comple recovery except for the persistence of a small cavity, as show by later roentgenograms. The last short wave treatment w given Feb. 12, 1936. She returned to the Children's Clinic o request from time to time. March 14 a note was made that sh was going to school and feeling well and that there was n cough or expectoration. She remained free from symptom until September, when there developed a cough, which persisted When she was seen October 31 her temperature was 101.2 F The sputum was purulent and of foul odor. There were dulnes and bronchial breathing over the lower part of the right lung A roentgenogram revealed an abscess involving the entire middle lobe (fig. 4). November 5 she was sent to the Massachusetts Memorial Hospitals with a temperature of 101 F. There the abscess was drained in a three stage procedure. At operation it was found to involve the entire middle lobe. During the following months the patient slowly recovered, and she was discharged April 26, 1937, with a small sinus still present.

Therapy.—A 4 meter wavelength was used with large electrodes 3 cm. from the skin. Treatments were given daily, lasting from ten to forty-five minutes. The total number of treatments was 113 and they extended from July 1, 1935, to Feb. 12, 1936.

This case seemed to be a striking demonstration of the curative value of short wave therapy in lung abscess. The symptoms rapidly disappeared, but a small cavity persisted in spite of 113 short wave treatments given over a period of more than six months. The patient remained clinically well for over a year. Then symptoms returned, the abscess enlarged and surgical treatment was necessary. The case teaches that a lung abscess is not cured until the cavity is closed and replaced by scar tissue.

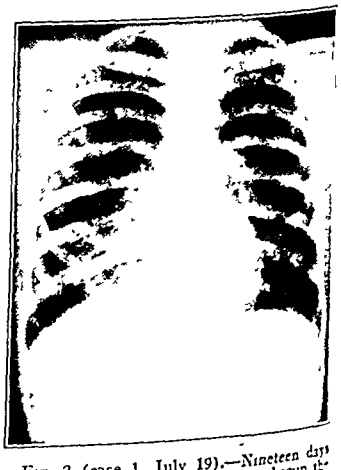

Fig 2 (case 1, July 19).—Nineteen days after short wave treatments were begun the shadow was reduced in size, but there was a large cavity in the lung with a fluid level clearly visible.

CASE 2.—*History.*—A. G., a single woman aged 29, had a tonsillectomy April 7, 1938, and nine days later, April 16, there was a sudden rise of temperature with chill and cough. From the onset until admission to the Diagnostic Hospital of the New England Medical Center April 21 the temperature had ranged from 100 to 102 F. and there had been severe pain in the lower right lateral region of the chest, with increasing cough and sputum amounting to as much as 100 Gm. daily. On two occasions it had a foul odor and taste. On admission *the patient* appeared acutely ill. There was an almost con-

22. Vosschulte, K., and Schwarzhoff, E.: Spontanheilung, interne Behandlung und Indikation zum chirurgischen Engriff beim Lungenabzess, München. med. Wchnschr. **85**: 580 (April 12) *1938.*

tinuous cough, with choking attacks and the expectoration of foul-smelling sputum. There was slight dulness over the lower part of the right lung posteriorly. In this area a few moist rales were present. The sputum contained a few spirochetes, fusiform bacilli and many elastic fibers. No tubercle bacilli were found. Roentgenograms April 21 showed an area of homogeneous density in the mid third of the right lung in which a fluid level was seen. May 5, fourteen days after admission, the cavity appeared much larger. The clinical course was marked by continuous fever during the first nine days. On the ninth day the patient coughed up 717 Gm. of sputum in twenty-four hours. After this the amount of sputum ranged between 100 and 200 Gm. The temperature was unchanged. The blood sedimentation rate remained the same. It was 24 mm. in one hour April 22 and also May 5.

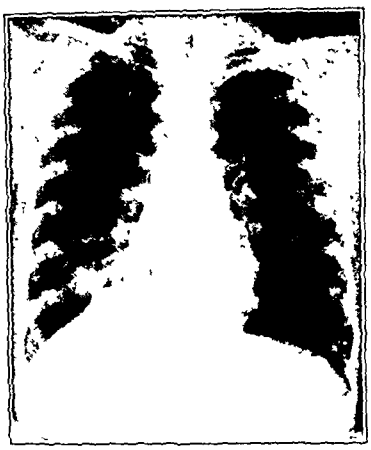

Fig. 3 (case 1, August 23).—The abscess cavity can no longer be discerned. It is apparently replaced by dense tissue.

The patient received either 0.1 Gm. or 0.05 Gm. of neoarsphenamine on three occasions. This treatment was discontinued on account of a marked reaction after the third treatment.

Therapy.—Daily treatments were given except for the four days from April 27 to May 2. A 6 meter wavelength was used with large electrodes, each placed 6 cm. from the skin. The duration of the single treatments was from five to fifteen minutes. Severe paroxysms of coughing, together with the weakened condition, made treatments longer than fifteen minutes unadvisable. The total number of treatments was eight.

Course.—There was no change in the clinical picture, but there was a definite increase in the size of the cavity. Therefore the patient was transferred to the New England Deaconness Hospital, where a large abscess cavity was found and drained by Dr. Overholt. She made a good recovery.

In this case of lung abscess following tonsillectomy, short wave therapy was given over a rather short period, but as the patient's symptoms were not diminished and as the abscess increased in size it seemed proper to resort to surgical treatment. In view of the small number of treatments given one might not be justified in recording this case as a failure of short wave therapy. On the other hand, eight treatments given in two weeks failed to produce the slightest amelioration of the symptoms.

CHRONIC LUNG ABSCESS

CASE 3.—*History.*—G. B., a housewife aged 35, had pneumonia of the lower lobe of the right lung in 1928 and since then had raised from 20 to 30 Gm. of sputum daily. Between 1929 and 1932 several hemoptyses occurred. For the past few years she had felt fairly well and had been able to do a moderate amount of housework. On examination Sept. 19, 1935, slight pallor was noted. There was flatness over the right side of the chest; here a few sibilant and consonating rales were heard. No tubercle bacilli or elastic tissue could be found in the sputum. The sedimentation rate was 17 mm. in one hour. There was no anemia. Roentgenograms showed a faint triangular shadow in the middle of the right lung, which was interpreted as due to an abscess. During the following days the sputum averaged 50 Gm. The hemoglobin content was 89 per cent and the red cell count 4.7 million per cubic millimeter. The temperature was normal. Bronchoscopic examination supported the diagnosis of abscess of the lung.

Therapy.—Radiation with a 4 meter wave was given daily for from fifteen to forty minutes with electrodes 20 cm. in diameter placed 4 cm. from the skin.

Course.—Treatment was continued from September 23 to December 23, when she was discharged. The results of x-ray examination remained unchanged, and when she left the hospital she was raising from 30 to 48 Gm. of mucopurulent odorless sputum daily.

This patient had a very chronic and benign form of lung abscess. There was no improvement, although short wave treatment was given for three months.

CASE 4.—*History.*—R. H., a business man aged 56, had a febrile pulmonary infection in December 1933 following exposure to cold. A roentgenogram of the chest in June 1934 showed changes suggestive of bronchopneumonia. Cough had persisted since then. In September 1934 an x-ray examination revealed an abscess in the lower lobe of the left lung, as did one done in April 1935. On admission June 6, 1935, he stated that the cough and sputum had increased during the previous three weeks and that the sputum was purulent. There was dulness over the lower lobe of the left lung. Occasional medium and coarse rales were heard over this region. The temperature during the stay in the hospital did not rise above 99.6 F.; the average pulse rate was 95. The blood sedimentation rate was 6 mm. in one hour (Westergren). A blood count showed 7,100 leukocytes and 5.2 million erythrocytes per cubic millimeter and a hemoglobin content of 100 per cent. The sputum amounted to between 12 and 60 Gm. in twenty-four hours; there were many elastic fibers in one specimen but no tubercle bacilli. X-ray examination revealed in the eighth intercostal space of the left lung a definite round shadow 3 cm. in diameter apparently half filled with fluid.

Therapy.—Thirty-four treatments were given, a 4 meter wavelength being used. Large electrodes were placed 4 cm. from the skin of the chest. For the first fortnight a short wave treatment was given daily, and then a treatment was omitted two or three times a week.

Course.—No improvement in the patient's general condition was noticed. A roentgenogram made at the end of treatment showed no change in the size or the appearance of the abscess.

This case represents a benign form of a well encapsulated abscess without signs of activity. Despite prolonged treatment there was no change in the size of the abscess.

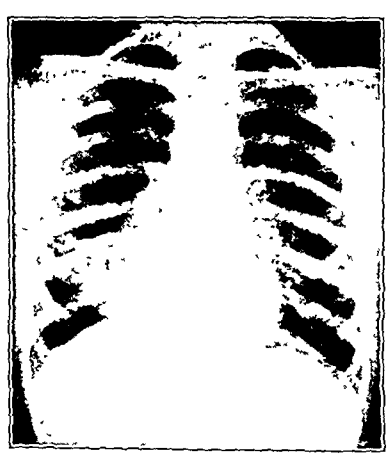

Fig. 4 (case 1, Nov. 5, 1936).—The cavity, with a fluid level, is larger than in July 1935.

CASE 5.—*History.*—H. R., a boy aged 9 years, swallowed a blade of grass Oct. 4, 1935, and apparently had pneumonia one week later. Subsequently a diagnosis of lung abscess was made and confirmed by x-ray examination. In January 1936 he was placed in a hospital outside Boston, where aspiration of the abscess was attempted. Empyema then developed. Two ribs were resected and 500 cc. of pus removed. Improvement followed and the temperature fell to normal. He was admitted to the Diagnostic Hospital of the New England Medical Center February 17. He was pale and undernourished, and there was a foul odor to the breath. There was a draining sinus in the right lower part of the chest, with dulness on percussion over this part and diminished breath sounds. The hemoglobin content was 70 per cent, the leukocytes numbered 17,200 per cubic millimeter and the sedimentation rate was 50 mm. in one hour. The sputum contained no acid-fast

bacilli or elastic fibers and varied in amount from 60 to 120 Gm. X-ray examination revealed a marked infiltration of the lower lobe of the right lung with an ill defined lower margin and a curved outline of the upper margin. He was in the hospital nearly two months and had a mild fever throughout his stay. The average pulse rate was 100.

Therapy.—Daily irradiation was performed with a wavelength of 4 meters and large electrodes placed about 3 cm. from the skin. The total number of treatments was forty-two.

Course.—There was no change in the amount of sputum, temperature or general condition during his stay at the hospital. He was transferred to the Massachusetts Memorial Hospitals, where lobectomy was attempted July 17. He did not survive the operation.

This was a case of severe lung abscess due to a foreign body. The condition did not respond to short wave therapy.

CASE 6.—*History.*—E. Y., a machine tender aged 21, who showed the first signs of pulmonary involvement in April 1936, when he began to cough and raise blood-streaked sputum, was under observation in the Diagnostic Hospital from June 2 to June 25. There was dulness over the right side of the chest. Diminished breath sounds and moist rales were present over the entire right lung. The leukocytes numbered 28,200 per cubic millimeter. The blood sedimentation rate was 52 mm. in one hour. X-ray examination showed a large area of infiltration in the upper lobe of the right lung with areas suggestive of destruction of lung tissue. During his first stay in the hospital the infiltration lessened and the sputum decreased from 100 to 25 Gm. A roentgenogram taken on discharge showed remarkable regression of the infiltration, but a definite area of softening had developed. He improved for a time. On August 9 cough returned, and he was readmitted August 16. The sputum had increased in amount and had developed a foul odor. It amounted to between 30 and 50 Gm. in twenty-four hours. Only a single elastic fiber was found in the sputum; there were no tubercle bacilli. The temperature varied from normal to 103 F. X-ray examination August 20 showed an infiltration involving two thirds of the upper lobe of the right lung with a questionable fluid level.

Therapy.—Radiation with a 6 meter wavelength was given daily for nine days for from fifteen to thirty minutes, large electrodes placed 4 cm. from the skin being used.

Course.—The temperature fell somewhat after a few days but later rose again. X-ray examination September 14 showed extension of the infiltration toward the base with a fluid level present. The patient was transferred to the Massachusetts Memorial Hospitals, where September 19 operation (drainage of two lung abscesses and resection of three ribs) was performed. He died October 6. Autopsy revealed multiple abscesses in the lower lobe of the left lung.

This patient when treated was in a toxic condition. He was in no way benefited by short wave treatments and finally died in spite of operation.

CASE 7.—*History.*—F. R., an Italian shoemaker aged 44, became ill Feb. 12, 1937, when fever, cough and headache developed. X-ray examination four weeks later showed an isolated abscess with a fluid level in the lower lobe of the left lung. Operation was advised in October but refused. Later cough, expectoration and loss of weight became more pronounced. The patient entered the Diagnostic Hospital November 17. He showed signs of chronic infection and pallor and coughed frequently. He weighed 98 pounds (44 Kg.). The temperature was 100 F., the respiratory rate 36 and the pulse rate 88. There were slight dulness over the lower lobe of the left lung and a slight decrease in the tactile fremitus over the base of the left lung, where numerous moist rales were heard after coughing. A blood count showed 14,500 leukocytes and 4.5 million erythrocytes per cubic millimeter and a hemoglobin content of 65 per cent. The sedimentation rate was 78 mm. in one hour (Westergren method). The sputum ranged in amount from 160 to 460 Gm. in twenty-four hours and had a foul odor; no spirochetes were found. X-ray examination on admission showed a dense shadow over the lower lobe of the left lung.

Therapy.—The patient was given thirty-six treatments with a 6 meter wavelength for twenty minutes daily from November 19 to January 6, except on Sundays and holidays. The electrodes were 20 cm. in diameter and were placed 4 cm. from the skin of the left lower part of the chest.

Course.—The temperature varied between 100 and 102 F. and the respiratory rate between 30 and 36. The pulse remained accelerated. There was a slight increase in weight but no change in general condition of the results of x-ray examination. December 27 the sedimentation rate had risen to 127 mm. in an hour.

The patient was transferred to the surgical department of the Peter Bent Brigham Hospital, where he died after drainage was performed. An autopsy revealed multiple abscesses in the left lung.

In this case progressive multiple abscess formation was not influenced by short wave therapy.

CASE 8.—*History.*—J. B., a man aged 22, who in March 1937, on the ninth day after an appendectomy, was seized with a shaking chill followed by a severe cough and high fever, the following day raised fetid sputum. A week later an x-ray examination showed an infiltration of the upper lobe of the left lung. Cough and fever continued, and about 30 Gm. of foul sputum was raised daily. He lost 20 pounds (9 Kg.). During the summer the symptoms gradually disappeared. Through the fall and early winter he was fairly well and regained 20 pounds. In February 1938, three weeks before admission, he was seized with cough, pain in the right upper part of the chest and fever. The fever persisted for a week. On admission, March 30, his weight was slightly diminished, his general condition was fair, there was no anemia and he had moderate cough. A few sibilant rales were heard over the base of the left lung; otherwise the physical examination gave negative results. A roentgenogram of the chest showed two cavities in the apex of the lower lobe of the left lung. The sputum contained many elastic fibers but no tubercle bacilli or spirochetes.

Therapy.—Daily short wave treatments for from ten to twenty minutes with a 6 meter wavelength were given. Large electrodes were used over the lower lobe of the left lung at a distance of 10 cm. in front and 4 cm. in back. The total number of treatments was nineteen.

Course.—During hospitalization he remained afebrile except for five days (April 18-April 23), when he had an increase of sputum, headache and a rise of temperature to 102 F. The sputum ranged in amount from 75 to 250 Gm. daily, contained a little blood occasionally and had a fetid odor. There was no improvement in the results of examination on discharge. He was transferred to the New England Deaconness Hospital, where Dr. Overholt did a three stage drainage of the lung abscesses. He made a good recovery.

Chronic abscesses in the lower lobe of the left lung causing relatively mild symptoms were uninfluenced by short wave therapy.

COMMENT

We have published our results because we believe they indicate clearly that short wave therapy is of far less value in the treatment of lung abscess than the advocates of this method claim. We are especially doubtful of the possibility of curing chronic abscesses with short waves. There is a certain danger, as recently pointed out by Vosschulte and Schwarzhoff,[22] that patients may be lost by persistence in conservative treatment who might be saved by surgical intervention. Whether or not short wave therapy will cure acute lung abscesses is still undecided. As an analysis of the

reported cases shows that eighty-five of 128 patients with lung abscess, or 66 per cent, recovered, the evidence is clear that a further trial of this method should be made with patients seen early in the disease before surgical intervention is resorted to. We have used throughout the most powerful apparatus of European manufacture, identical with the best equipment employed by those who have reported cures, large Schliephake electrodes, and have given daily treatments of the same duration as those by others who have had success. Dieker,[11] using exactly the same technic that we employed in most of our cases, a large output of energy, a wavelength of 6 meters and a distance from the skin of at least 4 cm., reported fifteen recoveries in sixteen cases. The only reasonable change we can make in technic is to increase the distance of the electrodes from the chest. In view of the experience of Liebesny [8] and others we shall use in the future an air gap between the electrode and the skin of 10 cm.

SUMMARY

In two cases of acute and in six cases of chronic abscess of the lung, short wave therapy was not successful in effecting a cure.

30 Bennet Street.

BILE SALT SOLUTIONS IN INFECTIONS WITH BETA HEMOLYTIC STREPTOCOCCI

THEIR THERAPEUTIC AND PROPHYLACTIC PROPERTIES

L. H. SCHMIDT, PH.D.
AND
DOUGLAS B. REMSEN, M.D.
CINCINNATI

Hilgermann [1] has advocated parenteral administration of small amounts of sodium taurocholate as an effective prophylactic and therapeutic measure in treating infections caused by beta hemolytic streptococci. He offered the following theoretical basis for its use: Injection of small quantities of sodium taurocholate brings about death and solution of small numbers of streptococci, from which antigenic substances are liberated; these antigens induce an active immunity to the invading organism by stimulating formation of protective antibodies. No convincing evidence was offered to support this theory. Hilgermann's experiments with mice were preliminary and meagerly detailed; Stoeckel's [2] more complete work only partially supported Hilgermann's claims. The results of the clinical use of sodium taurocholate [3] were suggestive but not at all conclusive, owing principally to the lack of extensive bacteriologic data but also to the use of other forms of treatment along with the bile salt therapy.

From the Christ Hospital Research Institute.

1. Hilgermann, Robert: Die Chemotherapie der Streptokokkeninfektion, München. med. Wchnschr. **77**: 1970-1971 (Nov. 14) 1930; Chemotherapie mit gallensauren Alkalien ein sicheres Heilmittel bei Streptokokkeninfektionen, Zentralbl. f. Gynäk. **60**: 1090-1096 (May 9) 1936; Chemotherapie und Prophylaxe der Streptokokkeninfektion mittels gallensauren Alkalien, ibid. **60**: 2290-2294 (Sept. 26) 1936.

2. Stoeckel, K. H.: Tierexperimentelle Untersuchungen mit dem Chemotherapeutikum Taurolin (Hilgermann), Ztschr. f. Immunitätsforsch. u. exper. Therap. **91**: 285-298 (Oct. 15) 1937.

3. Schäfer, Günther: Die Erfolge der Chemotherapie mit gallensauren Alkalien bei Puerperalfieber und bei gynakologischen Streptokokkeninfektionen, Zentralbl. f. Gynäk. **60**: 1096-1107 (May 9) 1936.

Our attention was brought to the status of this problem by the late Dr. John E. Greiwe, who had obtained a supply of Hilgermann's bile salt preparation (prepared by Schering-Kahlbaum). Greiwe had used this material clinically without success. This clinical failure and the obvious theoretical objections to the use of any bile salt preparation for this purpose suggested the need of more extensive experimental work than Hilgermann had reported.

We have performed both prophylactic and therapeutic experiments with mice, using (1) Hilgermann's preparation and (2) a solution prepared in our own laboratory containing sodium taurocholate and sodium deoxycholate. These solutions were tested against infections produced with different strains of beta hemolytic streptococci. Our results have been uniformly negative; in every experiment, regardless of the amount of the therapeutic agent administered or the time or mode of administration, the treated animals have died as rapidly as the controls.

EXPERIMENTS

Therapeutic Solutions.—Hilgermann has never given the exact composition of his sodium taurocholate solution, either in publications or in communications to Greiwe. It is said to be a dilute solution of sodium taurocholate in a special buffer, the nature of which is not disclosed. Qualitative examination gave the following results: The solution gave a very weak Pettenkofer reaction and a negative Gregory-Pascoe reaction. Unless the buffer inhibited the ordinary reactions of sodium taurocholate, this observation indicates that if a bile salt is present it is more likely a derivative of deoxycholic acid than of cholic acid. Alkaline hydrolysis liberated aminonitrogen equivalent to that contained in a 0.44 per cent solution of sodium taurodeoxycholate. Sulfur was present. The solution had a p_H of 8.2 and contained 0.6 per cent of phenol.

The solution prepared in our laboratory contained 0.5 per cent sodium taurocholate, 0.05 per cent sodium deoxycholate and 0.5 per cent phenol, all in tenth molar aminoacetic acid buffer at p_H 8.2.

Administration: The solutions were injected, both subcutaneously and intraperitoneally, in amounts varying from 0.5 cc. of the undiluted solutions to 0.5 cc. of 1:10,000,000 dilutions. When used prophylactically these amounts were injected forty-eight, twenty-four and twelve hours prior to infection. When they were used therapeutically, some groups of animals were treated immediately and others two and four hours after infection.

Streptococci.—Five strains of beta hemolytic streptococci were studied. Two, Schw and C203, were supplied by Dr. Perrin H. Long of Johns Hopkins University; these were highly virulent for mice, 10^{-8} cc. of a sixteen hour blood broth culture killing mice within forty-eight hours. The other three strains were freshly isolated from human beings and passed through numerous mice until maximum virulence was obtained; two were as virulent as Schw and C203; the third was of low virulence, 10^{-4} cc. of a sixteen hour culture being required to kill a mouse. In our experiments all mice were infected intraperitoneally with ten minimum lethal doses of the streptococci.

RESULTS

The results of a typical experiment, that with C203, are shown in the accompanying table. Our results have been entirely negative; neither Hilgermann's preparation nor our own possessed prophylactic or therapeutic properties.

This observation is contrary to those reported by Hilgermann and Stoeckel. A comparison of our work with Hilgermann's is impossible, since he has not presented any experimental data. Stoeckel used a beta hemolytic streptococcus of low virulence; his control mice infected with 10^{-1} cc. of a twenty-four hour broth culture survived for three days. Three of seven mice infected with 0.1 cc. of that culture and treated with 0.5 cc. of 1:100,000 and 1:1,000,000 dilutions of Hilgermann's preparation survived; mice treated with 0.5 cc. of a 1:10,000 dilution died, as did the controls.

Effects of Prophylactic and Therapeutic Treatment on the Survival Time of Mice Infected with Beta Hemolytic Streptococci (C203)

No. of Mice in Group	Time of Administration	Solution Administered*	Amount Injected (Cc.)	Average Survival Time (Hours)
6	48 hours prior to infection	H	0.5	40
6	48 hours prior to infection	S and R	0.5	43
6	24 hours prior to infection	H	0.5	41
6	24 hours prior to infection	S and R	0.5	41
6	12 hours prior to infection	H	0.5	42
10	Controls	None	0.0	43
6	On infection	H	0.5	44
6	On infection	S and R	0.5	46
6	On infection	H	0.5×10^{-1}	41
6	On infection	S and R	0.5×10^{-1}	43
10	Controls	None	...	47
10	On infection	H	0.5×10^{-3}	41
10	On infection	H	0.5×10^{-4}	42
10	On infection	H	0.5×10^{-5}	41
10	On infection	H	0.5×10^{-6}	42
10	On infection	H	0.5×10^{-7}	42
10	Controls	None	...	43

* "H" refers to the Schering-Kahlbaum preparation; "S and R," to the Schmidt and Remsen preparation. Prophylactic and therapeutic injections were made subcutaneously into mice infected intraperitoneally with 10^{-7} cc. of sixteen hour blood broth culture.

This observation would indicate that the effective dose of sodium taurocholate is infinitesimal, not more than 0.00005 mg. per mouse. It is difficult to explain Stoeckel's results, but it is to be noted that he used only sixteen mice in his entire experiment and that of the treated animals only three of thirteen survived.

Theoretically it seems improbable that bile salt solutions such as Hilgermann's could have curative or prophylactic properties in streptococcic infections. It is well known that hemolytic streptococci are slightly if at all soluble in solutions of bile salts. Even assuming that a few strains might be bile soluble, the amounts of bile salt used would be much too small to effect solution and larger quantities would probably be toxic. In addition it must be remembered that the liver removes bile salts from the circulating blood very rapidly, and any sodium taurocholate injected would have slight opportunity of reaching streptococci in isolated lesions.

PURPURA HAEMORRHAGICA

WITH ESPECIAL REFERENCE TO PERMANENCE OF REMISSION FOLLOWING SPLENECTOMY

STUART L. VAUGHAN, M.D.
AND
THEW WRIGHT, M.D.
BUFFALO

In 1916 Kaznelson [1] reported the first splenectomy as a therapeutic measure in a case of idiopathic purpura haemorrhagica. Since then this procedure has been carried out in hundreds of cases and has become a standard practice in many clinics all over the world. Few persons doubt the effectiveness of this form of treatment in properly selected cases not only in rehabilitating those persons who are recurrently or chronically invalided but also in actually preserving the lives of some patients who suffer from acute hemorrhagic phenomena.

Splenectomy is still an empirical procedure, since the role of the spleen in the disease and the mechanism by which its removal causes remission are unknown. Until the fundamental nature of the condition is understood, the study of all its phases will continue to be of interest. One such phase pertains to the permanence of remissions produced by splenectomy.

One of us (T. W.) performed one of the first splenectomies, if not the first, for purpura in the western hemisphere. The case is still under observation and is presented here (case 1), together with five others in which operation was done more than ten years ago.

REPORT OF CASES

CASE 1.—This case was reported in 1923 by Bowen,[2] with follow-up records covering the first four months after operation.

J. S., a man aged 22, was admitted to the Buffalo General Hospital May 16, 1922. Abnormal bleeding was noticed first at the age of 4 years, after a laceration above the eye. At 5 he bled profusely when, during an attack of diphtheria, the membrane was pulled off. At 7 profuse bleeding followed adenoidectomy. At 11 he began to have jacksonian epilepsy associated with visual disturbances, localized occipital headache and partial paralysis. For the full eighteen years up to the time of hospitalization he had suffered from petechiae and ecchymoses of the skin and from epistaxis and recently he had suffered from hemorrhages from the bowel. Because of the symptoms his school life and later his work had been highly irregular. An acute exacerbation of bleeding phenomena began one week before admission.

Physical examination revealed extreme pallor, ecchymoses, old and new hemorrhages into the eye and exaggerated reflexes in the right arm. The lymph nodes and the spleen were not palpable.

Examination of the blood showed 1,648,000 erythrocytes, 18 per cent hemoglobin and 4,800 leukocytes, with 75 per cent polymorphonuclears, 18 per cent lymphocytes and 7 per cent monocytes. There were 2,500 platelets. The bleeding time was twenty minutes, the clotting time eight minutes and the clot nonretractile. Occult blood was found in the stool repeatedly.

During the interval between admission and operation (three months) he had one convulsive attack. He was given one blood transfusion, which was followed by clinical improvement. One month after admission a petechial eruption developed and the bleeding time was found to be two hours and twenty-five minutes. A few days later the spleen became palpable, and

still later there was bleeding from the gums and intestine. Splenectomy was performed August 28. Convalescence was accompanied with complete cessation of bleeding symptoms, except for one mild attack of epistaxis and ecchymosis two months after operation.

A few days after being discharged from the hospital he was readmitted with an attack of "catarrhal jaundice" from which he recovered. Shortly after this he secured a position as street-car motorman, which he held without interruption for eight years. Since then he has worked continuously as maintenance

man for a real estate concern, doing various types of outdoor and indoor work, of which the major part is painting.

Reexamination April 29, 1938, almost sixteen years after operation, revealed that except for the slight attack of bleeding one month after operation he had had no hemorrhagic symptoms since the splenectomy. In 1932 he had had his tonsils removed without difficulty. There had been no convulsive seizures of any kind, and paralysis had disappeared. Occasionally he had headaches similar to those which formerly occurred with the seizures. His vision was excellent in both eyes, but he noted spots before the right eye occasionally.

He was healthy appearing and muscular. The right fundus showed several small patches of retinal atrophy. The reflexes were normal and equal in the two arms.

CASE 2.—E. M., a married white woman aged 42, was admitted to the Buffalo General Hospital Jan. 22, 1926. The present illness began in October 1924 with an attack of "shingles," followed by multiple hemorrhages from the uterus and continuous bleeding from the gums of such severity that she often awoke at night with her mouth full of blood. There

were almost daily epistaxis and the development of hemorrhagic spots in the skin varying in size from that of a pinhead to that of a pea. She lost strength and 15 pounds (6.8 Kg.) in weight. Spots appeared before her right eye and there was ringing in the ears.

She had suffered from prolonged and profuse menstrual flow since puberty. She had borne three children. Hemorrhage had followed the last delivery. The last child suffered from frequent severe attacks of epistaxis and bled abnormally after trauma.

Examination revealed emaciation and marked pallor. The skin showed generalized purpura. Bleeding points were present in the gums. The lymph nodes and the spleen were not enlarged. No abnormality was found on pelvic examination to account for the bleeding.

Examination of the blood showed 820,000 erythrocytes, 23 per cent hemoglobin and 4,500 leukocytes, with 40 per cent polymorphonuclears, 58 per cent lymphocytes and 2 per cent monocytes. The bleeding time was twenty-four minutes and the clotting time one-half minute. There were 12,000 platelets, the urea nitrogen content was 29.4 mg. per hundred cubic centimeters and the serum bilirubin content was too low to estimate.

During the first ten weeks following admission she received nine blood transfusions. These were followed by subjective improvement, and bleeding from the gums and into the skin ceased. Uterine bleeding continued despite a uterine pack.

Splenectomy was performed April 10. Convalescence was uneventful except for mild uterine bleeding for five days. The patient was discharged from the hospital May 2, showing remarkable general improvement.

Patient 1 in 1938, fifteen and one-half years after splenectomy.

It has not been possible to obtain reports on the blood since she left the hospital. However, a recent report from her physician revealed the fact that there has been no marked recurrence of hemorrhagic symptoms.

CASE 3.—K. R., an unmarried white woman aged 26, admitted to the Buffalo General Hospital March 15, 1927, had always "bruised" easily. However, she was well until 1923, when her menstrual periods began to be prolonged and the flow profuse. In 1926 purpura, bleeding gums and marked increase in the menstrual flow developed. After that she complained of progressively increasing weakness and shortness of breath.

She was well developed and had marked pallor. No purpura was present. The gums bled easily on slight pressure. The lymph nodes were not enlarged and the spleen was palpable indistinctly.

Examination of the blood showed 1,600,000 erythrocytes, 27 per cent hemoglobin and 5,500 leukocytes, with 81 per cent polymorphonuclears and 19 per cent lymphocytes. There were 24,000 platelets. The bleeding time was prolonged, the clotting time normal and the clot nonretractile.

Two blood transfusions were given a week apart. There was general improvement, and except for an attack of gingival bleeding March 31 there were no hemorrhagic phenomena for about one month. However, uterine bleeding recurred. Ultraviolet irradiation had no effect on either the symptoms or the blood. Three transfusions at short intervals were followed by only slight amelioration of the bleeding

Splenectomy was performed July 14. Except for an attack of pleurisy on the left side, convalescence was uneventful, and up to the present time there has been no single recurrence of abnormal bleeding.

CASE 4.—E. K., a white boy aged 3 years, admitted to the Children's Hospital July 27, 1927, had been perfectly well until May 30, when he had a spontaneous profuse nosebleed lasting an hour. The second attack occurred a week later. This was followed by numerous attacks at short intervals. At this time large ecchymoses began to appear on slight trauma A few days before admission he had three severe attacks of epistaxis in one day. Petechiae and hemorrhages from the mouth, intestine and bladder were not observed.

Physical examination revealed marked pallor and many large ecchymoses No nasal lesion was found that could account for the recurrent epistaxis. The lymph nodes and the spleen were not enlarged.

Examination of the blood showed 2,520,000 erythrocytes, 55 per cent hemoglobin and 15,300 leukocytes, with 72 per cent polymorphonuclears, 23 per cent lymphocytes and 5 per cent monocytes. There were 3,000 platelets. The bleeding time was ten minutes, the clotting time five minutes and the clot nonretractile.

Epistaxis continued in the hospital, and splenectomy was performed August 3. Convalescence was uneventful and he was discharged August 29.

Observations have been made at intervals after the operation and there has been no recurrence of bleeding. He is now a healthy, well developed boy of 14.

CASE 5.—I P., a married white woman aged 30, was admitted to the Buffalo General Hospital April 9, 1928. This case was described by Kahn[3] in 1932, but follow-up notes were not included in his report.

Seven years before admission she bled continuously for eight weeks after childbirth After that menstruation became irregular, prolonged and profuse. Severe epistaxis occurred one week before each period. Ecchymoses appeared after slight trauma. For about four months before admission these symptoms were exaggerated, and bleeding from the gums became severe. Roentgen treatment failed to control uterine bleeding

Examination showed marked pallor, and purpuric spots were present on the left leg. The lymph nodes and the spleen were not enlarged.

Examination of the blood showed 2,330,000 erythrocytes, 25 per cent hemoglobin and 8,200 leukocytes, with 82 per cent polymorphonuclears and 18 per cent lymphocytes. There were 36,000 platelets. The bleeding time was twenty minutes and the clotting time three and one-half minutes.

The patient received one blood transfusion and other treatment to control the bleeding, with no effect. Splenectomy was performed April 17. Convalescence was stormy and complicated by pleurisy with effusion. However, all bleeding ceased, and she was discharged from the hospital May 28

It has not been possible to obtain reports of the state of the blood since then, but at the time of writing the patient is known to be alive and well and to have had no recurrence of abnormal bleeding.

CASE 6.—J. R., a white girl aged 13, admitted to the Buffalo General Hospital April 24, 1928, had had bleeding symptoms for the first time five years previously, following scarlatina and measles. Since then there had been recurrent attacks of

epistaxis, bleeding gums and purpura About one year before admission she underwent tonsillectomy and bled profusely. A short time after this her menstrual periods began; they were irregular and prolonged, and the flow was profuse.

The patient was well developed, with pronounced pallor Petechial hemorrhages were present on the chest, abdomen and extremities. The gums were actively bleeding. The lymph nodes and the spleen were not enlarged

Examination of the blood showed 3,580,000 erythrocytes, 45 per cent hemoglobin and 8,000 leukocytes. There were 20,000 platelets. The bleeding time was prolonged and the clotting time normal.

Preparations for splenectomy were begun at once, and after two transfusions the operation was performed May 19. Postoperative convalescence was uneventful, and there has been no recurrence of abnormal bleeding to date Menstruation has been regular each month, each period lasting six or seven days, with light flow. The patient has led a normally active life, having finished school and undergone training as a nurse, with no loss of time because of illness.

SUMMARY AND COMMENT

In this paper we have reported the results of splenectomy in six cases of purpura haemorrhagica. The periods of postoperative observation have varied from ten to fifteen and one-half years. As far as can be determined, this group of patients has been followed longer than any group thus far reported. Only

3. Kahn, M. E.: Abnormal Uterine Bleeding in Blood Dyscrasias, J. A. M. A. 99:1563 (Nov. 5) 1932.

Whipple,[4] Geggie[5] and Giffin[6] have reported cases observed longer than ten years. However, records of some fifty-three cases observed from five to thirteen years were found. These included the cases just mentioned and those of Beneke,[7] Solway,[8] Myers[9] and Brown and Elliott.[10] This makes the total of cases observed from five to fifteen and one-half years about fifty-nine.

Although detailed records are not available, it would seem that in the great majority of these cases there was complete relief from symptoms and that the remissions were permanent to the end of the observation period. In the minority there were recurrences of hemorrhagic phenomena, usually of mild types. Only one case[6] was found in which severe bleeding occurred more than five years after splenectomy. It was that of a girl in whom severe metrorrhagia developed at the onset of puberty five years after splenectomy and after a long period of good health. This patient died.

Our series illustrates a few interesting and important points that have been mentioned by other writers. The first of these concerns the selection of cases for splenectomy. By far the best and most convincing results were obtained in cases in which the diagnosis of recurring idiopathic purpura haemorrhagica was unequivocal. This was true in cases 1, 3, 5 and 6. In these cases all evidence of history, physical examination and laboratory data supported the diagnosis. Recovery was characteristic and permanent. However, case 2 was atypical with respect to the age of the patient at the onset of illness, the comparatively short duration and the leukocyte picture. The patient recovered slowly and incompletely, and the platelets failed to increase in the characteristic manner. This is the type of case in which the decision to perform splenectomy is reached with some reluctance, as though the procedure is rather forced on the physician. Case 4 fails also to conform to the group of ideal cases, although the results were excellent. This was a case of juvenile purpura of short duration. What the end result would have been with more conservative treatment cannot be said. However, with increasing knowledge of this disease it has come to be recognized that a high proportion of affected children recover spontaneously. On the other hand, similar cases are known in which acute hemorrhagic phenomena developed and death followed in spite of heroic measures. It seems to us that the question of therapeutic indication in juvenile purpura is still unsettled and that there is much to be said for prompt splenectomy before the patient becomes a poor operative risk.

A second interesting point concerns the platelet response and associated phenomena in relation to splenectomy. Brown and Elliott[10] and others have described a platelet curve which has come to be regarded as rather typical. A sharp rise occurs usually within forty-eight hours, to reach a peak in about ten days. This is followed by a secondary fall, sometimes to a subnormal level, at which point a mild recurrence of bleeding is noted. In case 1 of the present series there was such a course, and we have observed this phenomenon in several more recent cases. However, it is not present in all. In some cases, for example case 3, the initial increase brings the platelet level within normal limits, where it is maintained without perceptible fluctuation for long periods. In others the initial rise is extremely slow (case 4). In a number of cases the platelet level has remained subnormal for months or years and yet no recurrence of bleeding has resulted. In most of these, other evidences of hemorrhagic diathesis, for example prolonged bleeding time, may be demonstrated.

In other words, the majority of typical cases of recurring purpura respond to splenectomy in a rather characteristic manner, but a minority do not. In spite of numerous suggestions with regard to prognosis and prevention of this unfavorable response, there seems to be no absolute method of foretelling the result in an individual case.

Brown and Elliott[10] described postoperative pulmonary complications on the left side in two cases. In the present series, patients 3 and 5 showed similar complications. In both the involvement seemed to be limited to the pleura, one having pain and friction rub and the other a large effusion.

CONCLUSIONS

1. Of six patients with purpura haemorrhagica observed from ten to fifteen and one-half years after splenectomy, all continue to be free from bleeding phenomena, and four of these are known to show normal platelet levels.

2. The best and most convincing results were seen when the preoperative diagnosis of recurring idiopathic purpura haemorrhagica was unequivocal.

THE RELATION OF THE PHYSICIAN TO THE TUBERCULOUS PATIENT

ALFRED L. KRUGER, M.D.

JERSEY CITY, N. J.

The past decade can truly be called the beginning of a new era in collapse therapy in pulmonary tuberculosis. It is not my purpose at this time to enter into any discussion of the various forms of collapse now being utilized in the treatment of pulmonary tuberculosis but rather to dwell on and consider the psychologic and mental phase in the treatment of this disease.

In an analysis of records concerning patients discharged from the Hudson County Tuberculosis Hospital I noted that four times as many patients who were not receiving any form of collapse therapy signed a release as opposed to those who were. In an effort to ascertain the cause for this, three reasons presented themselves: (1) a feeling of well being, (2) conditions at home requiring their return to work, (3) the patient not sufficiently aware of the importance of bed rest in the treatment of tuberculosis and not educated properly as to the advantages of the sanatorium or hospital. With the knowledge in mind that a goodly number of the patients who signed a release in the past returned to the sanatorium with their lesion much more advanced in extent, and also remembering the definite danger that these patients present in carrying the infection to those with whom they might come into contact, we are

From the Tuberculosis Service of Dr. B. S. Pollak, Medical Director, Hudson County Tuberculosis Hospital.

attempting to guide our efforts toward the creation of a better understanding of each and every patient so that we may aid in directing them toward their goal of a life of usefulness to themselves and to society.

Many patients who are admitted to the sanatorium are not acutely ill and except for a slight cough or a sudden hemoptysis were not aware that anything was wrong with their physical condition. In the mass tuberculin testing that is now going on in various parts of the country, many cases of tuberculosis are being discovered that are entirely asymptomatic. I do not think it beyond the experience of every physician dealing with tuberculosis to say that in these patients, and especially in those who are the bread earners of a family, the news is received with some degree of shock. Especially is this true among those who recall stories of the fearful "consumption" and are not aware of what can be done today with most cases if obtained soon enough. I believe that the way a person is going to react to the knowledge that he has tuberculosis and will have to remain in a sanatorium for a long time depends on two factors: (1) his inherent characteristics, whether his tendency is toward an introvert or extrovert type, and (2) his station in life at the moment, whether or not he has any responsibilities, such as a family to support. It therefore behooves the physician, when he makes a diagnosis of tuberculosis, to study the type of patient that he has in hand. Especially is this true if he is going to treat the individual.

INTROVERTS AND EXTROVERTS

Jung has classified the human psychology into two groups: the introverts and the extroverts. Extroversion may be defined as the turning of an interest outward toward some object. Introversion, on the other hand, is a recession of interest from the object toward the subject or the contemplation of one's own thoughts and feelings. We do not believe that the tuberculous patients can be classified into these two groups as these represent the two extremes, but in each individual is the inherent tendency to lean more or less toward one or the other extreme. And when the individual develops tuberculosis that tendency becomes somewhat more manifest. I agree with Wolepor [1] in that we do not believe that there is any specific abnormal state in tuberculosis and that the neurasthenic manifestations encountered in tuberculous patients are not specific to tuberculosis alone but are the same as are not infrequently seen in individuals with any protracted illness. It is with the two extreme types and particularly with the introvert that the doctor must turn psychiatrist. For after all, as Noyes [2] defines it, psychiatry is "primarily concerned with the behavior of the human organism as a unitary system engaged in adjustment to its environment." That is exactly what the physician dealing with tuberculous patients must do: adjust and adapt them to their illness as close to the point of contentment as is possible, instilling within them the hope and certainty that they will soon recover and return to their former usefulness to society. In no other disease is this so important, for here the individual must be confined to a bed rest regimen for a number of months and he must be made to believe in the need for such treatment, and preferably in a sanatorium.

The extrovert is characteristically carefree and unconcerned about his condition. The problem that confronts the physician is to gain the confidence of the patient and to institute an educational program, explaining the need for prolonged treatment if the patient is to make satisfactory progress. Occasionally one will encounter a patient who does not understand the necessity for the need of intensive treatment. Here one must be frankly outspoken and attempt to show the patient what may happen if he fails to heed the physician's advice. The patient must be made to realize that he is a sick person in spite of his apparent well-being. He must be convinced of the fact that tuberculosis, when discovered early, may be easily controlled, whereas, when the disease is of a more advanced type, it is more difficult to obtain a satisfactory result. In order to obtain the full cooperation of the patient, it is essential that he be advised concerning the development and progress of the disease through the medium of educational propaganda, which must be conveyed to him in order that he may fully comprehend the significance of the entire situation. It is at this time that the physician in charge must make an indelible impression on his patient. An intelligent presentation of all details concerning the patient's particular involvement will in many instances mark the success or failure of the case in question.

It is with the introvert that we must use the greatest of discretion. He has kept his troubles to himself, for his best defense has been to keep his troubles hidden. It is this type of individual that should be prevailed on to share his innermost thoughts with the physician if the physician anticipates any results. He must not be allowed to become depressed, for I am convinced that a happy patient with a happy, healthy state of mind is a most desirable asset in fighting a chronic disease such as tuberculosis. On the other hand, I condemn the practice of minimizing a patient's lesion, such as diagnosing an infiltrate as a "bronchitis" so as to avoid any "embarrassment" to the patient. I only too often see patients who state that their physician, several months prior to admission, told them that they had a "little bronchitis" or a "tiny spot on the lung" and advised only a couple of weeks rest in bed. Such misleading statements or errors in diagnosis are just too frequent. However, when one has a patient in the sanatorium with the diagnosis of tuberculosis, in a certain few select cases I believe it perfectly justifiable to minimize somewhat the extent of the process. Those patients who are apprehensive and worried about themselves must be reassured and convinced that their trouble is not too far advanced and that with time they will recover. An attitude of optimism must be assumed by the doctor and imbued in the patient. I have noted in some of these cases that the mere mention of the word "cavity" has caused them to become panicky and apprehensive.

CASE 1.—T. O., a white man aged 35, was first admitted to the institution in February 1937 with a left sided pleurisy with effusion. Three years previously he had been treated medically for a mild hyperthyroid state with apparently good results. The fluid was aspirated on one occasion, a clear straw-colored fluid being obtained with no underlying parenchymal lesion noted on x-ray examination and after two months he was discharged. At that time it was seen that he was quite apprehensive and nervous but the knowledge that he had no definite pulmonary lesion soon cheered him. Following discharge he returned every three months for check-up and x-ray examination. In May 1938 a roentgenogram showed a small cavity in the right infraclavicular region, for which he was hospitalized. In view

1. Wolepor, Ben: The Mind and Tuberculosis, Am. Rev. Tuberc. 19: 314 (March) 1929.
2. Noyes, A. P.: Modern Clinical Psychiatry, Philadelphia, W. B. Saunders Company, 1934.

of his previous mental state and his fear of tuberculosis, he was told that he had an infiltrative lesion in his lung which required hospitalization. Pneumothorax was attempted but no free space was found. During all this time he had occasional "spells" of depression when he would become deeply concerned about his general health, but a few words of encouragement would soon put him at ease. One day, while talking to one of the nurses, he learned that he had a cavity in his lung and a dramatic change took place. He became exceedingly despondent, his appetite became poor and his entire demeanor was that of a "lost man." It was only after repeated talks with him, in which the size of the antrum was greatly minimized and evidence presented that a cavity could heal, that he was made to return to a more cheerful state of mind with the hope of recovering completely.

Here was a patient who was in the hospital and who was apprehensive and nervous about his physical condition, but who at the same time was most cooperative. In this type of individual I feel justified in minimizing the extent of the lesion, as long as it makes the patient maintain a cheerful and hopeful outlook and he continues to be cooperative.

ATTITUDE OF THE PHYSICIAN

I believe it wise, when making staff rounds, not to discuss the progress of the case in front of the patient, except in the form of encouragement, as the patient will listen intently and invariably misinterpret every statement. The physician should devote as much time as possible to obtain a sympathetic understanding with the patient and discuss at length any problem that may be brought up, no matter how trivial it may seem. These individuals should be encouraged to keep interested in the news of the day and I heartily endorse the widespread use of the radio. Its effects on the well-being of the patients have been so encouraging that in the new Hudson County Tuberculosis Hospital, which is now ready for occupancy, every bed is supplied with an individual ear-set, so that a patient may have the choice of listening to one of four different programs without in any way interfering with the other patients in the ward, should they desire to listen to another station or take a nap.

We have noted in a number of cases, especially of the introvert type, that, when pneumothorax is attempted and found to be ineffective because of an obliterative pleuritis, the patients will become despondent and feel that their only chance for recovery is lost. We have pretty well obviated this apparent setback by thoroughly explaining to them when pneumothorax is suggested that this procedure is merely an adjunct in the treatment of tuberculosis; that they will improve with bed rest alone, but that if pneumothorax is tried and proved to be successful it will help to rest the lung a little more and tend to hasten the recovery. But by no means is the thought conveyed that it is the treatment *par excellence*. In every ward in the sanatorium there must be one or more patients on a bed rest regimen who are improving. Pointing these patients out to the new arrival on whom pneumothorax has been tried unsuccessfully will do much in reassuring them.

In a sanatorium one constantly has to contend with requests from patients to be discharged. Particularly is this true among those who are on bed rest and are getting along fairly well. They feel that they can return home and continue with the same sort of treatment. With a very few exceptions I have found this not to be true. The majority of those who sign a release become careless about carrying out the fundamentals of the treatment and soon have to return because of reactivation of the lesion. This group presents a real problem not only to themselves but to the others with whom they come in contact. It is with this group that the physician must become frank and outspoken and stress the dangers involved. To obtain the cooperation of the patient and to have him fully comprehend the significance of his intentions, it frequently will be beneficial to cite as an instance the individual with whom the patient is familiar, who, for the reason of having refused advice, had to return with an advanced lesion. The earnestness and sincerity with which such statements are submitted to the patient will frequently have such a desired effect and persuade the patient to remain. The patient must be made to realize the seriousness of his disease. He must be made to realize that his ultimate recovery depends entirely on the extent of his cooperation with the physician.

One thing must be emphasized to all tuberculous patients, that rest means not only physical rest but also mental rest and that one cannot be subordinated to the other. The object of physical rest is to diminish the work of the lungs by diminishing the number and extent of the respiratory excursions. Yet, what good is such physical rest if the patient maintains a state of high nervous tension as seen in the neurasthenic type of individual? It is not infrequently noted that patients with extensive pulmonary involvement who are cheerful and mentally stable show a favorable progress. Ishigami [3] explains this on the presence of a comparatively high opsonic index. On the other hand, patients with neurasthenic tendencies showed a lowering of their opsonic during the period of mental upset with systemic upset and general decline.

MEMBERS OF THE FAMILY

The tuberculous person must be shielded from the cares and responsibilities of home and business and I have had, time and time again, to caution friends and members of the family from bringing any news to the patient which may in any way disturb him. Because of this I feel that, whenever feasible, sanatorium care for the patient is the desirable thing, for here the individual is more or less isolated from home influences, which, although well meant, are not always to the patient's best interests and, in addition, he is under constant supervision with the knowledge that he is in the same hospital with a number of others similarly afflicted and all having the same goal. Also, from a public health standpoint, his chances of spreading his infection are minimized.

CASE 2.—R. V. B., a white woman aged 21, a secretary, was admitted to the Tuberculosis Service of the Jersey City Medical Center Nov. 6, 1937. Prior to her admission she had been treated at another institution, where pneumothorax had been started on the right side May 17 and on the left side on June 15, 1937. Refills had been continued on the right side up to the time of her admission but had been discontinued on the left side November 6 because of an adherent pleuritis over the cavity-bearing left upper lobe with a tiny residual pneumothorax pocket over the lower lobe. The right lung showed a 35 per cent selective collapse over the upper lobe with an antrum measuring 2 cm. in diameter in the upper lobe area.

It was noted that during the first three days the patient was extremely despondent with persistent nausea, anorexia and frequent crying spells. After many attempts she was finally prevailed on to unburden herself and she stated that a physician had told her that her left lung was "shot" and that nothing

3. Ishigami, Tohru: The Influence of Psychic Acts in the Progress of Pulmonary Tuberculosis, Am. Rev. Tuberc. 2: 470 (Oct.) 1918.

could be done for her, so that pneumothorax had been discontinued. Her father yielded the information that, since being told, she had become greatly depressed and appeared to be much worse. At the staff conference it was decided to continue with the pneumothorax on the right side for the sake of reinstilling in her the hope for some recovery, although it was felt that her ultimate prognosis was poor. Slowly but surely, by frequent visits and talks to the patient, she was finally made to realize that her left lung was not completely "shot" and that pneumothorax was not essential for recovery from tuberculosis. To illustrate the point more vividly, several patients on whom pneumothorax had been attempted but no free space obtained and who were recovering were brought to her bedside and shown to her to prove that a bed rest regimen could be sufficient to heal a lesion. The change in her during the next few days was remarkable. She became cheerful and her appetite slowly improved. The true state of affairs was presented to her father and he was warned against revealing this information to her. She got along fairly well as time went on and the cavity on the right side gradually closed. In May 1938 she received a letter from her sister telling her that she had heard that the pneumothorax on the right was going to be discontinued as it was ineffective. This was practically equivalent to pronouncing a death sentence on her, for she lapsed into a state similar to the one she was in when she was first admitted. This statement was entirely erroneous as we had no idea of doing this, but we reasoned that the father had revealed the true state of affairs to the "indiscreet" sister, who in part misinterpreted the statement to mean that we were going to discontinue the treatment on the right side. She was called in and the patient was finally convinced that her sister had been misinformed. She soon returned to her normal self and at the present time is one of the most cheerful patients in the hospital with as much hope as any of them.

In conclusion, I would make a plea for a more rational attitude toward the tuberculous patient, one of optimism and hope, for with both of these we shall find our task in combating this disease a much easier, happier and more fruitful one.

THE EFFECT OF NONSPECIFIC OPERATIONS ON ESSENTIAL HYPERTENSION

ITALO F. VOLINI, M.D.
AND
NATHAN FLAXMAN, M.D.
CHICAGO

Investigation of the literature on the operative therapy of essential hypertension indicates inadequate use of control studies. This is especially significant in relation to the question of whether nonspecific surgical measures influence hypertensive disease.

In 1930 Ayman [1] evaluated the therapeutic results in cases of essential hypertension by interpreting symptomatic relief. He stated that the successful treatment of essential hypertension by the use of many different drugs and methods of treatment has been reported at least 200 times in the decade 1920 to 1930. Since then an equal number of new types of treatment for essential hypertension have been introduced, many enthusiastically. They stay momentarily and then rapidly wane into obscurity.

At present a constantly increasing number of operations are being proposed and performed as treatment for essential hypertension.[2] We have analyzed these with the results published and, as Ayman [1] found previously, noted that the articles dealing with the surgical treatment of essential hypertension exhibit certain common features:

1. Complete or partial symptomatic relief is reported.
2. A moderate and occasionally a marked reduction in blood pressure is reported.
3. The degree of symptomatic relief is generally greater than the degree of reduction in blood pressure.
4. The degree of symptomatic relief is frequently out of all proportion to the reduction in blood pressure.
5. Marked symptomatic relief sometimes occurs without any reduction in blood pressure.

This report presents a comparison between the results of nonspecific surgical measures (e. g. hysterectomy, cholecystectomy, prostatectomy) and specific measures (e. g. extensive sympathectomy, splanchnic nerve resection, celiac ganglionectomy) performed on patients with essential hypertension. During the past nine years 1,500 cases of hypertensive heart disease have been studied. In fifty-two of these, various operations had been performed during the precardiac stage.

Of the surgical cases, twenty-seven are suitable for analysis. A total of twenty-eight operations were carried out. None of these were performed as direct treatment of the essential hypertension; they were incidental to it. However, many patients refused the necessary surgical measures because of their hypertension until, in an effort to gain consent, it was explained to them that operation might help their high blood pressure. There was no proved basis for this statement. It was used only as a means to attain an end, the operation being urgently indicated at the time.

All the patients except patient 21 were operated on in the Cook County Hospital. Later they returned to the hospital when congestive heart failure or other manifestations occurred. All deaths and autopsies listed took place in the Cook County Hospital. A record was kept of the preoperative and postoperative blood pressure, the type and duration of symptoms, how long the patient was symptom free postoperatively, the blood pressure when he was last seen and the outcome. Cases were not selected. We had no part in obtaining consent for operation, surgical planning or after-care in the majority of these cases. Our observations were routine studies of the factors which influence the course of hypertensive heart disease.

There were fifteen white (nine female and six male) and twelve Negro (ten female and two male) patients in this series. The ages varied from 26 to 72 years at the time of operation. Twelve (44.4 per cent) were under 40 and twenty-two (81.5 per cent) under 50 (table 1).

27	45	♂	W	220/150	170/120	Cholecystectomy, appendectomy	Symptom free 3 yr.	4 yr.	200/112	Decompensated when last seen, 4 years after operation

* Malignant hypertension proved by autopsy.

The seven general types of operation performed are indicated in table 2. Sixteen patients (59 per cent) had pelvic operations, mainly hysterectomy or panhysterectomy for large fibroids alone or combined with diseased ovaries and fallopian tubes.

The preoperative and postoperative blood pressures are indicated in table 3. Reductions were common but in no way related to the amount of symptomatic relief.

All patients were relieved of symptoms such as headache, pain in the chest, "nervousness," dizziness, fatigue, insomnia and palpitation, regardless of the type of operation performed.

The duration of the symptom-free stage varied from four months to nine years, averaging three and one-half years (table 4). As far as can be determined, the results were better in our cases than in any of the specific operations for essential hypertension. Yet our patients were certainly not operated on primarily for the essential hypertension. Any of the claims made for the efficacy of treatment of essential hypertension by specific surgical measures can be substantiated by our cases of nonspecific operation. It is contended that if a patient is able to return to his former occupation—if he is relieved of his subjective symptoms—that and that only determines the value of the operation. Our patients had at least seven different types of operation and obtained the same results. While enforced bed rest, operative hemorrhage, anesthesia, operative insult and traumatism and the administration of sedative drugs are common factors in both nonspecific and specific surgical procedures which possibly influence hypertension, we believe our results prove what Ayman [1] showed clearly, that the symptoms associated with uncomplicated essential hypertension may frequently be relieved by the suggestion inherent in any seriously and enthusiastically prescribed drug or means of therapy.

SUMMARY

The symptomatic relief and reduction in blood pressure resulting from nonspecific surgical measures (e. g. hysterectomy, prostatectomy, cholecystectomy) in the presence of essential hypertension are similar to and sometimes better than those obtained by specific procedures (extensive sympathectomy, splanchnic nerve resection, celiac ganglionectomy) performed especially for those purposes in the treatment of essential hypertension. The evidence presented justifies doubt of the indications for specific surgical treatment of essential hypertension and the results obtained from it.

Manson's Fortune Diminished Rapidly.—At the end of 1889 Manson returned to Scotland, where he had acquired an estate in the vicinity of his birthplace, and where he intended to pass the remainder of his days as a man of leisure; but luckily for posterity, fate had it otherwise. The large fortune that he had accumulated rapidly diminished in the face of the falling value of the Chinese dollar, so that in the ensuing year he was forced to begin work again, and descending upon London, he commenced a consulting practice at 21 Queen Anne Street. Although his reputation had been unequalled in the East, he found that it was not so easy to commence an uphill struggle at 46 years of age; but soon his connection began, and it was not long before he was appointed a physician to the Seamen's Hospital Society, with charge of beds in the Dreadnought Hospital at Greenwich.—Power, Sir D'Arcy: British Masters of Medicine, Baltimore, William Wood & Co., 1936.

Clinical Notes, Suggestions and New Instruments

SUBSEQUENT HISTORY OF A NEEDLE BROKEN OFF AND LOST IN THE UTERINE WALL DURING AN EMERGENCY OPERATION

JAMES N. BRAWNER JR., M.D., ATLANTA, GA.

Now and then a needle breaks off during an operation. As a rule, it is possible to recover the broken portion and remove it; sometimes it cannot be found.

In the case here reported a right tubal pregnancy had been removed. A few months later the patient was hurriedly admitted to the hospital and at once operated on for a rupture of the uterus during early pregnancy.

On account of the patient's alarming condition, quick action was necessary. During closure of the ruptured uterine wall the greater portion of a curved needle broke off and was lost in the wall of the uterus; it could not be located.

It was necessary to get the patient off the table at the earliest possible moment. The tear in the uterine wall was sutured and the abdomen closed.

The subsequent history of the needle is an interesting one.

REPORT OF CASE

First Admission.—M. McF., a Negress aged 22, was admitted to the Johns Hopkins Hospital Nov. 10, 1934, complaining of vaginal bleeding for seven weeks, abdominal pain, weakness, nausea and vomiting. She had menstruated normally from Aug. 20 to 23 and from Sept. 15 to 18, 1934. The history and results found on examination were typical of a ruptured tubal pregnancy on the right side. Immediate operation (performed by Dr. Erle Henriksen) confirmed this. A large, rather old pelvic hematoma was found in which the right tube and ovary were involved. Right salpingo-oophorectomy was done, the cornual portion of the tube being excised from the uterus with a small wedge of surrounding tissue. This defect was closed with figure of eight sutures of no. 2 plain catgut (fig. 1), and the right round ligament was used to cover the raw surface according to the Coffey technic. Convalescence was uneventful and the patient was discharged in good condition November 22.

Course.—For nearly three months the patient had been feeling well and returned to the outpatient clinic Feb. 18, 1935, for a follow-up examination. At this time she stated that she had menstruated normally from Dec. 13 to 18, 1934, and from Jan. 14 to 17, 1935, and was then several days past the expected date of her menstrual period. For three weeks she had had slight pain in the left lower quadrant of the abdomen. Examination revealed no abnormalities except the absence of the right adnexa. She returned March 2 stating that the abdominal discomfort persisted although it was never severe. There were no signs of pregnancy at this time, but on March 11 the uterus was found to be about twice the normal size and was firm; some tenderness was present in the left adnexal region but no masses were palpable. There had been no vaginal bleeding since her last menstrual period January 14. A possible tubal pregnancy on the left side was suspected, although an intra-uterine pregnancy seemed more likely, and nothing was evident to contraindicate continued observation in the outpatient department after she had been warned of more acute symptoms. She returned one week later, March 18, saying that sharp pains had been experienced in the left lower quadrant the day before, at which time she was nauseated and vomited. Examination was made and revealed tenderness in the left lower quadrant of the abdomen; the cervix was a little soft; there was no vaginal bleeding; the uterus was symmetrically enlarged, two and a half times its normal size; there was tenderness but there were no masses in the region of the left tube and ovary. Intra-uterine pregnancy was the impression at this

From the Department of Gynecology of the Johns Hopkins Hospital and University, Baltimore.

time. The patient left the examining table, dressed and was about to leave the clinic when she felt dizzy and weak, complained of a sudden, sharp pain in the upper part of the abdomen, and fainted.

Second Admission.—The patient was immediately admitted to the ward from the outpatient clinic March 18 with the tentative diagnosis of a ruptured left tubal pregnancy. The pulse was rapid, with a rate of from 130 to 140 a minute, and of poor quality; respirations were rapid and shallow. The abdomen was

Fig 1.—Appearance of the right uterine cornu after removal of a right tubal pregnancy.

distended There was generalized abdominal tenderness and muscle spasm and definite evidence of intra-abdominal free fluid. The usual treatment for shock was immediately administered. She was prepared for operation as quickly as possible.

Operation (performed by Dr Thomas Cullen).—Under gas-ether anesthesia a paramedian incision in the lower part of the abdomen was made Between 1,500 cc. and 2,000 cc. of fresh blood was free in the abdominal cavity. The left tube and ovary were normal. The uterus was symmetrically enlarged and soft, corresponding to a pregnancy of two or three months. There was a large rupture beginning at the right cornu, extending downward from 4 to 5 cm in the lateral wall of the uterus through which placental tissue and fetal membranes protruded from the uterine cavity (fig 2). The bleeding vessels were immediately controlled, edges of the tear were excised and a portion of the placenta was removed with blunt forceps The fetus was not encountered The laceration was repaired with several figure of eight sutures of plain catgut. In an attempt to control a small amount of bleeding from a needle hole in the uterus a small Ferguson needle was broken About three fourths of the needle was left in the myometrium, as the patient's condition did not allow time for further search. As stated before, the right tube and ovary had been removed previously. The proximal end of the round ligament, which had been severed from the uterus, was again sutured to the region of the right cornu. A large quantity of free blood was sponged from the abdominal cavity and the wound was closed in layers without drainage.

Pathologic Report.—The tissue removed for study consisted of parts of grossly normal appearing placenta with attached membranes and small pieces of myometrium which had been trimmed away from the edges of the laceration. Microscopic examination revealed normal placental tissue corresponding to a pregnancy of two or three months. The myometrium was interesting in that small areas of scar tissue were visible in addition to rather deep penetration of the trophoblastic tissue into the uterine wall. The outer, uninvaded smooth muscle was not more than 5 mm. in thickness.

Course.—During and after the operation 5 per cent dextrose was given intravenously, this being followed by a transfusion of 500 cc. of citrated blood. Gradual improvement followed. The hemoglobin determination, which had been 48 per cent (Sahli) on admission, had risen to 65 per cent the following day. Moderate vaginal bleeding persisted, and in view of this a light curettement was done April 8, very little tissue being obtained. After this vaginal bleeding was diminished her general condition was good, and on April 10 she was discharged after receiving contraceptive advice.

The vaginal bleeding ceased several days after discharge from the hospital. She returned to the outpatient clinic May 2, bringing with her the part of the needle which had broken off in the myometrium during the operation, stating that this had passed by the vagina without pain the day before. There were no complaints. Examination revealed the uterus normal

Fig 2.—Rupture of the right side of the uterus during an early pregnancy, occurring a few months after removal of a right tubal pregnancy. Forceps pulling away some of the fetal membranes

in shape, size and position though somewhat adherent. The left ovary was of normal size and slightly adherent and was not tender. Her condition was quite satisfactory when she was last seen.

This was a most happy termination of what might have been a difficult problem We have no record of a similar case having ever been observed in the Johns Hopkins Hospital.

478 Peachtree Street N E.

THE USE OF RABBIT ANTIPNEUMOCOCCUS SERUM IN THE TREATMENT OF ULCUS SERPENS

HAROLD G. SCHEIE, M.D., AND LEON H. COLLINS JR., M.D.
PHILADELPHIA

For years the more commonly accepted methods of treatment of ulcus serpens have been chemical disinfection, curettage, cautery by physical or chemical means, and a variety of surgical measures. Specific serum therapy has never been widely acclaimed, those using it having reported indifferent results.

Cheney [1] in 1922 voiced the opinion of most ophthalmologists by citing the failure of serum therapy on two counts: 1. In the majority of cases the pneumococci isolated from corneal ulcers were not suitable for serum therapy. At that time the only available potent antiserum was for the type I pneumococcus. In his series of twelve cases "group IV" pneumococci, for which no antiserum was available, were the usual organisms cultured. In reviewing the literature Newman [2] collected 131 cases of ulcus serpens. In only five was the condition caused by type I, and in ninety-seven it was caused by "group IV." 2. Owing to the avascular character of the cornea, serum administered intravenously could hardly be expected to penetrate it and influence the process.

Since the work of Cooper in subdividing the old pneumococcus "group IV" it has been possible to type the pneumococci obtained from such corneal ulcers. Originally "group IV" was subdivided into twenty-nine types. The evidence at present, however, indicates that type VI is similar to type XVI and type XV to type XXX. They may be typed by the Neufeld technic [3] in the manner that is used for the typing of pneumococci in the sputum. Specific rabbit pneumococcus antiserum for typing is now available in practically all portions of the United States. Recently this serum has been introduced for clinical use in the treatment of pneumonia caused by several different types of pneumococci, and more types are gradually being included. For experimental use it is available for the treatment of nearly every type. Rabbit pneumococcus antiserum offers the possibility of usefulness in the treatment of pneumococcic ulcers of the eye because of the smaller molecule of the rabbit antibody as compared with that of the horse antibody, and the higher antibody titer of rabbit antiserum as compared with that of horse antiserum. Because of its small size the rabbit antibody molecule appears to be able to penetrate more freely into inflammatory areas than does the horse antibody. This thought has been given some support by the studies of Horsfall and his associates.[4] If this is true, one of Cheney's objections is partially overcome.

REPORT OF CASE

F. S., a Negro aged 87, was admitted to the ophthalmologic service of the Hospital of the University of Pennsylvania June 1, 1938, giving a history of injury to his left eye by a twig while he was trimming a hedge on May 19. The following day considerable pain and lacrimation had been noted, which had persisted up to the admission to the hospital. The history and systemic review were of significance only in that he had been suffering gradual loss of vision for the past two years.

Physical examination gave essentially negative results aside from the ocular condition.

The right eye was normal except for an incipient senile cataract, giving 9/15 vision with a pinhole. The left eyelids were slightly swollen and marked blepharospasm was exhibited. A small amount of purulent discharge exuded from the palpebral fissure. The conjunctiva was diffusely and markedly injected and slightly chemotic. A rather deep and sharply excavated round corneal ulcer 3 mm. in diameter was seen over the pupillary area to the temporal and inferior side. Its center was stained brown by mild protein silver, which his family physician had prescribed. The nasal margin was undermined and grayish. A hypopyon of 1 mm. was present. The aqueous humor exhibited a marked flare. The pupil was miotic and fixed. The lens was cataractous, the vision being limited to perception of light. No discharge could be expressed from the nasolacrimal duct.

On admission, after material for cultures had been taken from the culdesac and the ulcer, treatment was immediately started with 1 per cent atropine twice daily, hot compresses and irrigations with mercurophen (sodium oxymercury orthonitrophenolate) 1:12,000 as frequently as needed to keep the eye free from discharge. One cc. of Pregl's iodine solution was injected subconjunctivally below the cornea. The nasolacrimal duct was irrigated and found to be patent. The ulcer during three days of this therapy spread, advancing nasally and downward. The hypopyon fluctuated from 1 to 2 mm. The cultures of material from the ulcer and culdesac were reported at this time as positive for type XXIII pneumococci, so the patient was given instillations of ethylhydrocupreine (optochin) hydrochloride 2 per cent aqueous solution four drops four times daily, since no specific serum could be obtained. This therapy was continued for two days, during which time the spread of the ulcer continued unabated. Then, five days after admission, an adequate supply of type XXIII antipneumococcus rabbit serum was made available, enabling us to discontinue the ethylhydrocupreine. Forty-nine thousand units of antiserum was given during the first twenty-four hours, 30,000 units intravenously, 15,000 units by instillation (one drop every fifteen minutes) and 4,000 units subconjunctivally. At the end of this time the ulcer looked distinctly cleaner and no increase in size was noted. There was little local reaction to the subconjunctival injection of antiserum. From this time on improvement continued, and four days after the giving of serum was started the ulcer began to epithelize from the temporal margin and the hypopyon disappeared. The patient was given daily injections of antiserum intravenously for four days, and then medication was stopped, a total of 134,000 units having been given by this route. One more injection June 8 of 2,000 units made a total of 6,000 units subconjunctivally. The instillations by drop were kept up nearly continuously every fifteen minutes for five days and intermittently for ten days longer, making 340,000 units by this method and a total of 480,000 units of antiserum. Sixteen days after the institution of specific therapy another culture of material from the left eye was made, and it was found to be negative. A blood culture, made as soon as the original culture of material from the eye was reported, was negative. X-ray examination showed the pulmonary fields to be clear. The patient was discharged from the ward on the twenty-third day, with only a fine crescent on the cornea which stained with fluorescein. This had been the location of the previously advancing nasal border of the ulcer. The conjunctival chemosis had disappeared and only moderate diffuse injection remained, as well as two posterior synechiae. No immediate or delayed serum reaction occurred.

The patient was followed in the outpatient department and last seen July 6, at which time no staining of the cornea was present and the eye had remained quiet. The scarring of the cornea was minimal, being of macular density. Unfortunately the visual result could not be determined because of the senile cataract.

COMMENT

When the age of the patient and the advanced condition of the ulcer before treatment are considered, the clinical course proved to be distinctly better than that which is usually encountered with pneumococcic ulcers of the cornea. The scarring was certainly less than should have been expected.

We feel that here is a neglected phase of ocular therapeutics, since the previous objections to antiserum therapy are no longer valid. Potent antiserum for the different types of pneumococci is now available. It is possible that rabbit antiserum is better able to penetrate the cornea than the previously used horse antiserum. Our purpose in reporting a single case is to draw attention to the further possibilities of the antiserum therapy of pneumococcic infections of the eye.

The serum was furnished by the Lederle Laboratories, Inc.

HEMIPLEGIA FOLLOWING INJECTION OF EPINEPHRINE HYDROCHLORIDE

EDMUND L. KEENEY, M.D., BALTIMORE

There is no previous record in the medical literature of hemiplegia in man brought on by an injection of epinephrine. However, Wilhelm Erb[1] in 1905 reported the production of cerebral hemorrhage in rabbits following injections of this substance. It is curious that epinephrine, because of its widespread and sometimes careless use by asthmatic patients, should not have been added before to the list of rare causes of hemiplegia along with antipneumococcus serum,[2] antidiphtheric serum,[3] insulin[4] and nicotine.[5]

REPORT OF CASE

History.—J. D., a white man aged 33, married, an electrician, was known to have had seasonal and perennial hay fever and bronchial asthma since the age of 10 years. For the last four years he had received specific therapy with tree, grass and ragweed pollens and also with the inhalants dust and orris root. With such therapy his condition was definitely improved, but at times fairly severe attacks of asthma developed. For relief from such attacks he used epinephrine in a nebulizer, and during more severe attacks it had been customary for his wife to administer subcutaneously to him injections of epinephrine hydrochloride. This she had done satisfactorily for three years.

His symptoms had been so severe during the last three ragweed seasons that it had been necessary to hospitalize him. However, during the first three weeks of the 1938 ragweed season and until the onset of his present illness, he had been comfortable and attended work by having his wife administer to him every evening 0.75 cc. of epinephrine in oil.[6]

The morning of August 29, he awakened with a mild attack of asthma, which he alleviated somewhat by using the nebulizer. However, in thirty minutes the asthma reappeared and his wife administered to him 0.5 cc. of the 1:1,000 solution of epinephrine hydrochloride. Immediately following the injection he experienced a violent, splitting headache and in a few seconds became unconscious. The train of symptoms appeared, as his wife described, in the length of time that it took her to walk from his bed, following the injection, to a chest of drawers where she kept the syringe.

Examination.—The patient was seen forty-five minutes later. He was lying flat in bed in a semicomatose state. The temperature was 99 F. and the pulse rate was 90. The respirations were slow and stertorous. Although he recognized me, he was unable to speak. The face was pale and the skin moist. There were no convulsive movements. The heart, lungs and abdomen were normal. The blood pressure was 120 systolic, 80 diastolic. (It is important to insert here that during the previous four years, while the patient was under constant observation and treatment for his allergic condition, the blood pressure, taken on many occasions, had never exceeded (110/70). The neurologic examination revealed the following:

Cranial Nerves: Second: The pupils were equal, round and regular, and reacted to light. Accommodation could not be tested. Visual fields could not be determined. The optic disks were clear and well defined. There were no hemorrhages or exudates.

Third, fourth and sixth: There was no ptosis of the lids. The ocular movements seemed normal.

Fifth: There was no apparent numbness of the face. The corneal reflexes were normal. The muscles of the jaw could not be tested.

Seventh: There was a moderate facial weakness on the right.

Eighth: The hearing, tested by watch and tuning fork, seemed normal.

Ninth, tenth and eleventh: The patient was unable to speak. The pharyngeal reflex was intact. The strength of the sternomastoid and trapezius muscles could not be tested.

Twelfth: The tongue was protruded to the right.

Motor System: The upper and lower extremities were flaccid, but there seemed to be more resistance to passive motion on the left side of the body. Tests for ataxia could not be made.

Sensory System: There was a definite reduction of cutaneous sensibility to touch and pain on both sides of the body, but there was less impairment on the left side.

Reflexes: The tendon reflexes were present in both the upper and lower extremities. There was no clonus. The right plantar reflex was definitely extensor.

In two hours the patient moved both legs and the left arm but was unable to move the right arm. In one week he was mentally clear but had difficulty in understanding what was said to him. The right arm could be lifted a few inches off the bed. For the first time he became aware that he was unable to see objects on the right of him with his left eye closed and that while reading he could see only half a word at a time. It was now possible to do a thorough neurologic examination.

The following observations were made by Dr. Frank R. Ford, the neurologic consultant.

Cranial Nerves: Second: The pupils were as described before. Examination of the visual fields disclosed a complete right homonymous hemianopia. The fundi were as described before.

Third, fourth and sixth: The conditions were as described before.

Seventh: There was a slight right-sided facial weakness.

Eighth: There was no subjective disturbance of hearing. Hearing was within normal range as tested with a watch and a tuning fork. There was no aural vertigo.

Ninth, tenth and eleventh: There was no weakness of the soft palate and no disturbance in swallowing. The pharyngeal reflex was present. There was no weakness of the sternomastoid and trapezius muscles.

Twelfth: The tongue protruded slightly to the right.

Motor System: There was some weakness of the right side of the face, of the right arm and of the right leg. The muscle tone was slightly increased in the right leg, although not obviously so in the right arm. The patient had a good deal of difficulty in using the right arm and leg. He missed his nose with the right finger but the movement suggested uncertainty rather than ataxia.

Sensory System: There was considerable reduction of cutaneous sensibility over the entire right side of the body, but there was not an absolute loss of touch or of pain. The sense of position, of passive movement, of stereognosis and of two-point sense were severely impaired on the right side of the body.

Reflexes: The tendon reflexes on the right side were as active as those on the left. There was no clonus. The right plantar reflex was definitely extensor.

Speech: The patient had some difficulty in finding words and forming sentences correctly. Articulation was fairly clear. He had great difficulty in understanding what was said to him and it was frequently impossible for him to grasp simple sentences, even when they were repeated.

It has been six weeks since the unfortunate accident occurred. The patient is now able to move the right arm above the head.

Dr. Leslie N. Gay gave the author the opportunity of reporting this case.

The gait is steady but he is uncertain of what the right leg is doing. The speech has improved and is more articulate, but he still has difficulty in understanding. With the exception of these changes the observations made on neurologic examination are identical with those enumerated before.

COMMENT

When the patient was first seen the development of the sudden hemiplegia could be attributed to either an angiospasm or a vascular hemorrhage due to a sudden hypertension. In either instance it was likely that the epinephrine by mistake had been injected directly into a small blood vessel; when the patient's wife was questioned, it became apparent that she had neglected to withdraw the plunger of the syringe before making the injection. Later on, because of the failure of the symptoms to disappear, it seemed more likely that there had been a vascular hemorrhage.

The neurologic consultant felt that there was a large lesion in the left hemisphere involving the visual pathways, the sensory pathways and some of the sensory speech areas and that the lesion must therefore involve the cortex of the inferior parietal region, where all these pathways are located. Because of the difficulty in speech, it was unlikely that the lesion could have been located in the left internal capsule.

The patient should improve slowly for a time, but it is improbable, because of the extent of the lesion, that he should make a complete recovery or ever be able to do more than the simplest work.

SUMMARY

A complete right-sided hemiplegia with a right homonymous hemianopia occurred in a young man without hypertension, following an injection of epinephrine hydrochloride.

DERMATITIS FROM INDUSTRIAL CONTACT WITH NICOTINIC ACID

R. M. WATROUS, M.D., NORTH CHICAGO, ILL.

Such pharmacologic work on nicotinic acid as has been reported has shown it to be a comparatively inert substance, aside from its specific effect in pellagra. A flushing of the skin with a sensation of warmth has been observed after its administration either intravenously or by mouth.[1] Rachmilewitz and Glueck[2] described the occurrence of an urticarial dermatitis with flushing of the face and severe itching in a patient with pellagra after he had received two 50 mg. doses of nicotinic acid orally. Chen, Rose and Robbins[3] determined the lethal dose for dogs to be 2,000 mg. per kilogram of body weight over a period of from eight to ten days—an enormous quantity compared with the therapeutic dose. These investigators found no irritant effect from 1 per cent solution of nicotinic acid injected intradermally. The following cases indicate that nicotinic acid is capable of producing a transient dermatitis in certain persons when it comes in contact with the skin.

REPORT OF CASES

CASE 1.—L. H., a white man aged 60, a nonsmoker, worked for an hour one afternoon making a granulation of nicotinic acid with excipients, in preparation for the molding of tablets. When he left work about two hours later, a physician called his attention to a diffuse erythema of all parts of the skin which had been exposed to the dust; his skin had the appearance of mild sunburn. That night the patient noticed moderate burning and itching of the affected skin and verified for himself its red appearance. The next morning the skin appeared and felt normal in every way, and it has continued so since.

CASE 2.—A. M., a white woman aged 38, an occasional smoker, began putting nicotinic acid tablets into bottles at 2 p. m. She continued the work the next day until 11 a. m. No symptoms were noticed until the following day, when she began to have severe itching and burning sensations on all portions of the skin not covered by the work clothing. On the affected areas there was a maculopapular rash with follicular distribution. The symptoms lasted with somewhat less severity until the next day, when I was able to verify the appearance and distribution of the rash. The skin was normal on the third day after exposure and has continued so since.

CASE 3.—A. M., a white woman aged 23, an occasional smoker, worked one morning bottling nicotinic acid tablets. At about 11:30 a. m. she began to notice a slight burning sensation on the exposed areas of skin and came to the dispensary, believing she had a "heat rash." At this time she had a diffuse erythema of all the exposed areas, sharply delimited by the lines of the clothing. On this erythematous base were small discrete maculopapules with follicular distribution. By 2:10 p. m. the reaction had faded considerably, and the exposed skin was washed with a cotton swab moistened with distilled water, the swab then being rinsed in distilled water. An unaffected area on the back was washed in a similar way, and the p_H of the washings determined immediately, with the following results: exposed skin, p_H 4.42; unexposed skin, p_H 4.35, and distilled water, p_H 6.10.

The next day the skin appeared and felt normal, and it has remained so since.

CASE 4.—J. B., a white woman aged 20, a nonsmoker, worked for an hour and a half putting nicotinic acid tablets into bottles. Nothing made her aware of any unusual condition of her skin until she happened to look in the mirror in the washroom and saw that her face appeared sunburned. She came to the dispensary to cooperate in the study, and her face was seen to be diffusely red except for two areas under the eyes, where her glasses had apparently prevented dust from settling. There was a mild burning or flushed sensation over the face at this time. The forearms, over the exposed portions, showed a fine macular rash with follicular distribution. No itching was complained of. Twenty-four hours later all subjective and objective manifestations had disappeared.

COMMENT

Other workers handling nicotinic acid under identical circumstances experienced no such reactions. The conditions under which the bottling of tablets was carried out allowed only a minimal exposure to the chemical; there was no visible dust, and the operator's hands never came in direct contact with the tablets.

To study further the effect of nicotinic acid on the skin, some powdered nicotinic acid was rubbed into a patch on the flexor surface of the forearm of eight volunteers. Four of these showed some reaction within a few hours, while the other four could detect no change whatever up to forty-eight hours after the application of the powder. Of the four showing reactions, three exhibited only a mild macular redness about the follicles, coming on from two to four hours after application of the chemical and lasting up to forty-eight hours, without itching or burning sensations. The fourth member of this group had a much more vigorous reaction, which came on only thirty minutes after contact and was accompanied with intense itching and burning. Some redness persisted in this subject for the next thirty-five hours. Curiously enough, this person showed no reaction at all when the same amount of nicotinic acid was rubbed into the skin of the forearm two weeks later. Five of these subjects were habitual smokers and three did not smoke. No correlation could be established between the use of nicotine and the susceptibility to the dermatitis.

The way in which nicotinic acid produces these local reactions is still obscure. That they are due to a local acid effect seems improbable because of the weak dissociation of nicotinic acid and because of the fact that not all skins respond to its application.

SUMMARY

Susceptibility to mild transient dermatitis due to contact with nicotinic acid during its industrial use is found only in certain persons at certain times, and its pathogenesis is at present unexplained. This condition is entirely related to industrial exposure to nicotinic acid and, to judge from existing literature, has no counterpart in clinical practice.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

JONES SUPER MOTOR-BASAL METABOLISM TESTER ACCEPTABLE

Manufacturer: Jones Metabolism Equipment Company, 315-323 South Honore Street, Chicago.

The Jones Super Motor-Basal Metabolism Tester is a closed circuit bellows type of metabolimeter using a motor blower to circulate the oxygen. It measures the time required by the patient to consume a measured liter of oxygen instead of computing the amount of oxygen consumed in a definite period of time. According to the firm, this method simplifies the computation. It is finished in white enamel with exposed parts of double chrome plate. The oxygen tank, chamber, and gage for measuring oxygen are supported by an iron frame. A superstructure carries the bellows, soda lime container, motor blower and recording device. Complete, the unit weighs approximately 50 pounds. It is 25 by 20 inches at the base and 50 inches high. With the breathing tubes in place, the overall length is 45 inches. It is readily portable on four 1½ inch casters.

Jones Super Motor-Basal Metabolism Tester.

The apparatus is connected to the patient by means of the conventional mouth piece and rubber tubes. A valve is provided which permits the patient to breathe room air until ready to begin the test. Then the valve is turned in the horizontal position so that the patient may breathe oxygen from the metabolimeter. The motor blower in the return circuit draws the oxygen and carbon dioxide from the patient and drives it through the soda lime back into the bellows. Negative pressure thus created at the mouth piece is very small.

Respiratory excursions are recorded on a moving plate, which drops at the rate of one inch per minute for eight minutes on the basal speed and in sixteen minutes at the superbasal position. A timer stops the apparatus. The movable plate operates on a plane perpendicular to that of the bellows. One end of the bellows is fixed. The recording pen is attached to the moving end. Two sizes of bellows are available. This increases the flexibility of the machine and makes it possible to handle patients of large size, irregular breathers, and individuals with a high oxygen consumption.

The Jones Motor-Basal Metabolism Tester was investigated in a clinic acceptable to the Council and gave satisfactory service, comparing favorably with other metabolism units with regard to accuracy and mechanical efficiency.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Jones Super Motor-Basal Metabolism Tester for inclusion in its list of accepted devices.

SANBORN WATERLESS METABOLISM TESTER ACCEPTABLE

Manufacturer: Sanborn Company, 39 Osborn Street, Cambridge, Mass.

Description: The Sanborn Waterless Metabolism Tester is a compact, semiportable unit that can be readily wheeled from room to room. It is 19 inches high by 13 inches long by 11 inches wide and weighs approximately 33 pounds. It may be furnished with or without a stand that is adjustable in height from 29 to 38 inches and occupies 2.7 square feet of floor space. This stand carries the oxygen tank and auxiliary apparatus and is equipped with large wheels which make it easy and safe to move. The tubes connecting the machine with the patient are 26 inches long.

This waterless machine has most of the features described for the Sanborn Motor Grafic Model E. I. S. (THE JOURNAL, Aug. 22, 1936, p. 587). It differs principally in having a vertically moving rubber bellows in place of a water spirometer. This bellows is supported by a chain passing over ball-bearing pulleys. The weight of the bellows is counterbalanced by a spring in the base.

Recording is made by a kymograph, 3⅜ inches in diameter, which carries a special wax coated chart rigidly held in place by special clamps. The electrically driven kymograph makes one complete revolution in ten minutes with an accuracy of plus or minus 0.16 per cent. The rulings in the chart are accurate to plus or minus 0.9 per cent.

The oxygen in the rubber bellows is circulated by means of a motor driven fan. This develops a positive pressure on the mouthpiece of 2 mm. of water. A valve inserted in the airline makes it possible for the operator to connect the patient with room air or oxygen at will.

METHODS OF USING THE METABOLISM TESTER

Two different methods of determining the rate of metabolism may be used with this waterless apparatus.

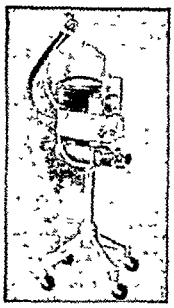
In the first, or short test, method a definite amount of oxygen, 1.25 liters, is placed in the bellows and the patient breathes from this until the oxygen is consumed. The time necessary for this is noted and a computation is made on this basis. No corrections for temperature and barometer are necessary in the short test. The volume of oxygen is measured in a rigid container and is not affected by barometer (atmospheric pressure), but the pressure applied to the oxygen within the container varies for different temperatures.

It is a fundamental law of physics that, when gas is in a rigid container, the volume is not affected by outside atmospheric pressure but varies with temperature and also by the pressure that is applied to the gas within the container. In the Waterless, oxygen gas is admitted to the container from a tank and the pressure is allowed to increase to a definite point required for the temperature that exists. A gage is calibrated to give the pressure that is required for 1.25 liters of oxygen at 0 C. and 760 mm. pressure.

This volume under compression is released into the rubber bellows from which the patient breathes. In the bellows, local conditions of atmospheric pressure and temperature may vary but there will still be 1.25 liters under standard conditions of 760 mm. and 0 C. By the test one finds the time it takes for a patient to consume this 1.25 liters and thus one obtains the patient's rate of oxygen consumption. This is the short test method.

In the second, or long test, method the bellows is filled with an excess of oxygen and the patient breathes this for a definite length of time, from ten to sixteen minutes. The amount of oxygen is then computed from the fall in the bellows. This fall is calibrated in terms of volume of oxygen.

In the long test method, temperature and barometer readings must be corrected for local conditions. These corrections are made in the same way that is customary in the common type of water-sealed metabolism testers. In the Waterless, the oxygen is let directly into the bellows through the pressure chamber with the bellows valve open. No reading of the gage or measurement by the pressure chamber is needed. The long test method may be used when the gage or pressure chamber which is required in the short test method is out of service. The unit volume of oxygen that is consumed during a given time is obtained from the chart, but the volume will be the volume that exists for a given temperature and barometer of local conditions. It must be corrected to 0 C. and 760 mm., and a correction of 2 per cent for humidity made.



VOLUME OXYGEN DELIVERED BY GAGE

The accuracy of the short test method depends on the accuracy with which the oxygen is delivered to the bellows. This point has been carefully checked by the following method: The volume of oxygen delivered by the apparatus was measured as it would be used by the patient. Two 2 liter flasks were connected in an air tight manner with rubber stoppers which were fitted with convenient inlet and outlet tubes. One of the flasks was filled with distilled water, which had been allowed to come to room temperature, and weighed. Enough water was placed

in the other flask to create a partial vacuum. Both flasks were weighed to the nearest tenth of a gram before displacement; then the full flask was connected to the metabolimeter mouthpiece and inverted at the same time as the one nearly empty. The inverted flasks were supported on adjustable ring stands. Oxygen was then admitted according to directions in the Sanborn instruction booklet. The nearly empty flask was lowered so as to create a partial vacuum and the oxygen was drawn over from machine to flask as a result. This was continued until the full amount of oxygen admitted to the bellows was in the displacement flask. Clamps were placed on the connection to the metabolimeter and the flasks were brought to a common level, disconnected and weighed. The difference in weight between the flask empty and the flask filled gave the amount of water displaced, and this gave, in turn, the volume of oxygen represented delivered by the gage to the bellows. The volume of oxygen collected during six trials averaged 1,444 cc., which, corrected for a temperature of 23 C., a barometer of 749 and a saturated water vapor of 20 mm., gave 1,278 cc. of dry oxygen delivered by the gage, the correct volume being 1,275 cc.

ACCURACY OF THE LONG TEST METHOD

In the long test method the oxygen is not measured by the gage but by the fall of the bellows. This is measured on the chart by a special scale, which should be calibrated for each instrument. The accuracy of this method depends on the resilience of the rubber bellows. As this changes in the course of time, the scale must be recalibrated. Since the accuracy of the apparatus may change slowly, it is advisable that the operator recheck the scale and the condition of the bellows or have this done by the firm at regular intervals.

Sanborn Waterless Metabolism Tester.

Careful measurements comparing the long test with the short test under identical conditions gave a difference in readings between the two of 3 per cent when the scale was used without correction.

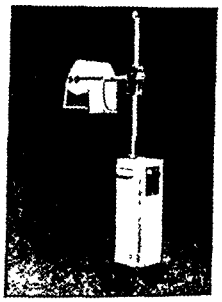
The long test method also requires an accurate reading of the temperature of the oxygen in the bellows. Temperatures are read during the long test by a mercurial thermometer with bulb directly in the breathing circuit. The average temperature is used to correct the volume of oxygen used.

OXYGEN LOSS FROM BELLOWS

The ability of the system to hold gas was tested by placing a weight of 1 Kg. on the bellows for forty-eight hours with all valves closed. The system lost 25 cc. of oxygen per hour. Without any pressure on the bellows, the loss was 3.7 cc. per hour. This indicates that under usual conditions the loss of oxygen is slight, 0.06 cc. per minute. Since the rubber bellows is clamped to the metal frame by a ring which compresses the rubber and is also cemented wherever a junction is effected with metal, the chance for oxygen loss during a metabolism determination is slight.

CLINICAL TESTS

The Sanborn Waterless Metabolism Tester, the short test method being used, was compared with the standard tested metabolimeter used in the clinic. Patients were tested consecutively on both machines under strictly comparable conditions. The determinations made on the different machines agreed within 2 per cent of one another. The Sanborn Waterless Metabolism Tester gave readings uniformly lower than the standard apparatus.

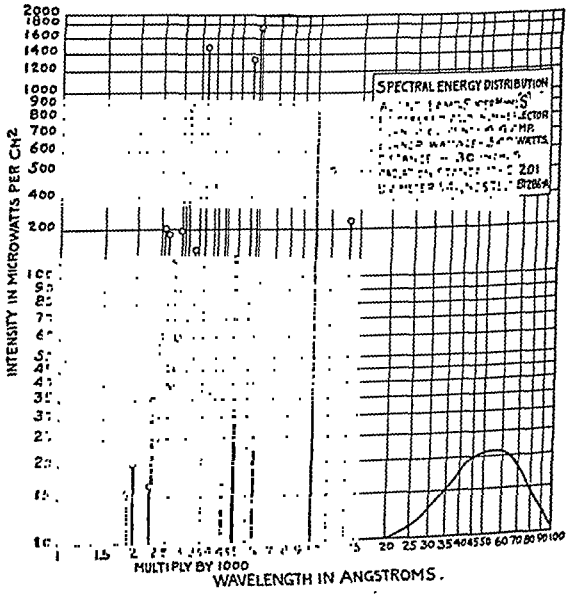


The tables in the pamphlet concerning calculation of the long test method have been checked with the slide rule and are found to be correct. The directions in the book of instructions describe the handling of the patient in a clear and concise manner and the operation of the apparatus correctly.

As the result of the Council's investigation, it seems evident that the Sanborn Waterless Metabolism Tester is accurate within the limits allowed for metabolism testing apparatus. In view of this report, the Council on Physical Therapy voted to include the Sanborn Waterless Metabolism Tester in its list of accepted devices.

HANOVIA SUPER ALPINE LAMP (MODELS S AND E) ACCEPTABLE

Manufacturer: Hanovia Chemical & Manufacturing Company, Chestnut Street and N. J. R. R. Avenue, Newark, N. J.



The Hanovia Super Alpine Lamp is a high pressure, high intensity quartz mercury arc lamp recommended for use in the hospital or physician's office. It is available in two models; Model S operates on alternating current, Model E on direct current. The burner is mounted at the focal point of a processed aluminum reflector which is supported within an outer hood, from which it is separated by a ventilation envelop, designed to assist in maintaining a comfortable hood temperature. A steel tape measure located at the side of the hood may be employed to measure the distance from the burner to the patient.

Hanovia Super Alpine Lamp.

The lamp hood is supported on the upright by means of a main swing head and cross arm, and is counterbalanced by a counterweight located within the upright. Vertical adjustment permits a minimum distance between the burner and floor of 48 inches and a maximum distance of 78 inches. The cross arm has a 10 inch travel, and at its maximum extension the burner is 24 inches from the upright, which rests on the transformer electrical control cabinet, in turn, integral with the base. This is mounted on four 4 inch rubber tired casters with clearance sufficient under the base for movement over a 2 inch door sill. The hospital unit in addition has a hospital-type carrier rigidly bolted to the base, especially adapting the lamp to ward work for bedridden patients. The approximate shipping weight of the entire unit is 200 pounds.

The electrical controls are located in a ventilated steel housing the top of which is 39 inches from the floor. A control panel is located on the side of the housing 32 inches from the floor. It comprises an electric supply switch, a ten point intensity control switch and an indicating instrument. The instrument for the Model S alternating current lamp is an ammeter which indicates the burner current. The instrument for the Model E direct current lamp is a voltmeter which indicates the burner voltage and polarity.

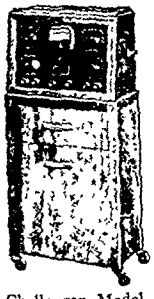
Spectral energy distribution.

The ultraviolet ray generating source, a self-starting burner, is a high pressure, low voltage mercury arc enclosed within a transparent fused quartz tubular vessel provided with metal lead-ins for the electric current which are sealed vacuum tight

rectly to the quartz tubing. An alternating current burner ntains self-heating incandescent solid activated electrodes and filling of mercury, with a rare gas for self-starting purposes. he direct current burner utilizes a mercury pool cathode and solid incandescent anode. Ultraviolet, visible and infra-red diations are emitted by both types of burners.

Model S (alternating current), operated on control No. 1, oduces an intensity of ultraviolet rays for wavelengths 3,130 ngstroms and shorter of 1,500 microwatts per square centi-eter and in ten steps to 2,500 microwatts per square centimeter. he maximum ultraviolet energy (after the lamp has warmed p) is sufficient to produce a first degree erythema (mild redden-ng) on the average person after an exposure of twenty seconds. he direct current lamps, Model E, are similar to the Model S intensity and erythema production.

The firm submitted evidence to substantiate the ability of ese lamps to produce suitable ultraviolet radiation to prevent r cure rickets in children, to prevent and cure infantile tetany.



The unit was tried out in a clinic acceptable to the Council nd gave satisfactory performance. It apparently emits the ame kind of radiation generated by other Hanovia lamps pre-iously accepted by the Council. The lamp also gives the same ype of service in the clinic as other Hanovia units have in the ast.

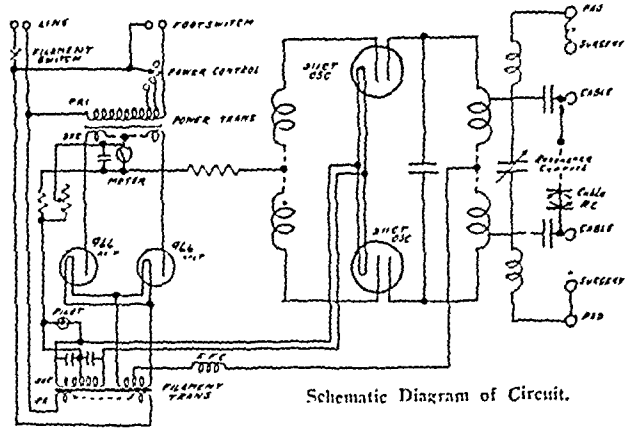
In view of the foregoing report, the Council on Physical Therapy voted to accept the Hanovia Super Alpine Lamp, Models S and E, for inclusion in its list of accepted devices.

"CHALLENGER" MODEL K SHORT WAVE UNITS ACCEPTABLE

Manufacturer: The Birtcher Corporation, 5087 Huntington Drive, North, Los Angeles.

The Challenger Model K Short Wave Units are recommended for medical and minor surgical uses. They are available in three cabinet styles designated 970, 980 and 990. The DeLuxe model (990) has a shipping weight of approximately 163 pounds. The dimensions of the cabinet are 45 inches high by 24 inches wide by 15 inches deep. The Standard model (980) comes in a two-piece cabinet and its shipping weight is approximately 125 pounds. The cabinet dimensions are 43 inches high by 20 inches wide by 14 inches deep. The small Portable model (970) comes in a black leatheret case with an electrode compartment and a removable lid. Its net weight is about 50 pounds and its dimensions are 13½ inches high by 19 inches wide by 15 inches deep.

Challenger Model "K" Short Wave Unit.



A tuned plate, tuned grid circuit is utilized and has a wavelength of approximately 16 meters. Two power and two separate rectifier tubes and a separate filament transformer are employed. Evidence submitted by the firm indicated that with an electromotive force of 116 volts and a measured input of 890 watts, the photoelectric cell and lamp load method being used, the output was 520 watts. With this load the output meter was evidently short circuited and no regard paid to the excursion of its needle.

In the Council test, with an electromotive force of 111 volts and an input of 660 watts, the output measured 270 watts. In this test the output meter was used and full scale reading regarded as full load of the apparatus.

With regard to the inductance calorimeter method, the firm submitted data showing that, with an electromotive force of 120 volts and a measured input of 970 watts and 3½ turns of the cable, the output was 445 watts.

In the Council test, in which a calorimeter was used according to specifications by the firm, and at an electromotive force of 107.5 volts and an input of 1,020 watts, the output was 417 watts. The milliammeter on the panel read about 600. In other words, the needle deflected as far as it could and would have gone farther had the scale been larger. Under this load the rectifier tubes began to flicker and the investigator recognized this as being an overload on the machine.

At a maximum input of 660 watts after two hours of continuous service the temperature rise in the outside windings of the transformer was 60 C., which is within limits acceptable to the Council.

Schematic Diagram of Circuit.

Evidence submitted by the firm for tissue heating was on a machine of similar hookup. It is given in the accompanying table.

Averages of Eight Observations

Deep Muscle			Oral	
Initial	Final		Initial	Final
		Pad Technic		
99.5	100.1		98.8	98.9
		Cuff Technic		
99.2	101.8		98.4	98.9
		Cable Technic		
99.3	102.7		98.8	98.1

The unit was tried out clinically by a qualified physician selected by the Council, who reports that it gave satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to include the "Challenger" Model K Short Wave Diathermy Units Nos. 970, 980 and 990 in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

LYXANTHINE-ASTIER NOT ACCEPTABLE FOR N. N. R.

Lyxanthine Astier is a polypharmacal mixture of ingredients marketed by the Gallia Laboratories, Inc., of New York City for the treatment of arthritis and related conditions.

The advertising circular for this product states, "Lyxanthine-Astier, a product of the research laboratories of Dr. P. Astier of Paris, France, and now prepared in the United States, is a compound containing an efficient combination of active principles amounting to 33%." The content of the various ingredients in 100 Gm. of the preparation is listed as follows:

"Iodo-propanol-sulphonate of sodium	12 Gm.
Bitartrate of lysidin	9 "
Calcium gluconate	12 "
Sodium bicarbonate	37 "
Tartartic acid	15 "
Citric acid	6 "
Powdered sugar	9 "
Oil of Lemon	several drops

The three ingredients apparently considered by the manufacturer to be of principal therapeutic value, since their actions are discussed individually, are iodo-propanol-sulfonate of sodium, which, it is claimed, "Combines the action of sulphur and iodine"; calcium gluconate, "An entirely organic radical of calcium"; and lysidin bitartrate, "A powerful solvent and eliminant of metabolic waste." The total content of these three ingredients is said to be 33 Gm. in 100 Gm. of Lyxanthine, which

agrees with the quantitative statement ". . . an efficient combination of active principles amounting to 33%." The content of other ingredients, which might conceivably be active constituents of the mixture, that is, sodium bicarbonate 37 per cent, or the tartaric and citric acids together, 21 per cent, would leave the physician and the patient in a dilemma regarding the manifold therapeutic possibilities, or contrariwise, of this complex mixture.

The indications for the use of Lyxanthine-Astier are stated to be "Arthritis—regardless of classification, whether mono- or poly-articular"; "Chronic rheumatism—whether articular or the so-called 'muscular rheumatism,'" gout; sciatica; neuritis, neuralgia; lumbago; gallstones; renal, ureteral or vesical calculus; "in hepatic disorder associated with arthritis," and several other conditions. The recommended course of treatment consists of ". . ." 20 consecutive days of medication followed by a 10 day rest period." According to the dosage recommendation of one teaspoonful daily (two teaspoonfuls in acute attacks), a patient would take daily a mixture of about 0.48 Gm. each of iodopropanol-sulfonate of sodium and calcium gluconate, 0.36 Gm. of lysidine bitartrate, the sodium salts resulting from the effervescent interaction of 1.48 Gm. of sodium bicarbonate, 0.6 Gm. of tartaric acid and 0.24 Gm. of citric acid dissolved in a glass of water; and twice as much if he decided he had ". . . to treat an acute attack." Continued alkalinity of the urine could promote precipitation of phosphates in the kidneys and bladder and possible formation of calculi with serious consequences. Hence, it is wholly unwarranted for the manufacturer to make such irresponsible recommendations on dosing with these alkalizers without warning the patient and physician of possible undesirable systemic disturbances, if not dangers to health. The ingredients chosen for special mention in the manufacturer's circular may be considered first.

IODO-PROPANOL-SULFONATE OF SODIUM

Iodo-propanol-sulfonate of sodium (CH_2I-$CHOH$-CH_2SO_3Na) is not listed in the United States Pharmacopeia, National Formulary, New and Nonofficial Remedies, Heffter-Heubner's Handbuch der experimentellen Pharmakologie or Seifert's Nebenwirkungen, nor is it listed in the *Quarterly Cumulative Index Medicus* to June 1938 or in *Chemical Abstracts* from 1916 to 1938.

There appears to be no discoverable published scientific evidence that iodo-propanol-sulfonate of sodium has a specific action in arthritis or in the other diseases listed by the manufacturer. That this agent "combines the action of sulphur and iodine" may be true, but it does not follow that these chemical elements, as used in Lyxanthine-Astier, are available for the ordinary actions of which they are capable when free or in simpler combinations.

Both iodine and sulfur have been recommended in various forms for the treatment of arthritis. For example, iodine has been used as potassium or sodium iodide, the iodoxybenzoate and iodocinchophen among the better known forms. Despite this usage, the therapeutic value of iodine in arthritis has never been conclusively demonstrated. The Council on Pharmacy and Chemistry does not recognize this therapeutic claim for iodine.

Sulfur has been widely used parenterally as a means of producing fever and also to some extent orally by using a combination of iodine and disodium-dithio-salicylate, which was recommended by Nardelli [1] for arthritis. Here again the specific value of the oral use of sulfur has not been found acceptable. The effectiveness of compounds like iodothiosal may be attributed to their salicylate content. Similarly also the effects of iodoxybenzoate and iodocinchophen may be ascribed to the oxybenzoate and the cinchophen, respectively.

LYSIDINE BITARTRATE

Lysidine, or ethylene-ethenyl diamine, was introduced by Ladenburg in 1894 as a uric acid solvent for use in the treatment of gout. Like piperazine, lycetol (dimethyl piperazine tartrate) and other compounds, which have been similarly recommended, it is a basic amine capable of forming a soluble salt of uric acid in the test tube.

In an exhaustive review of these compounds in 1917 Hanzlik [2] cited evidence to show that, although they dissolved uric acid in vitro, the presence of sodium chloride or urine greatly decreased this solvent power. As shown by Haskins [3] in 1916, large doses of lysidine given to men might slightly increase the uric acid content of the urine and also the uric acid dissolving power of the urine, particularly when sodium bicarbonate was given simultaneously. However, simple alkalization and dilution of the urine gave correspondingly effective results, without exposing the patient to the possible harmful effects (dermatitis) of lysidine.

Since the appearance of Hanzlik's review twenty-one years ago, no references to lysidine have been found in the *Quarterly Cumulative Index Medicus* up to June 1938. In 1935 a United States patent [4] was granted for the cinchoninic acid salts of the piperazines, with the claim that these were effective therapeutic agents in the treatment of arthritis. No clinical or experimental reports have been found to date to substantiate this claim.

Meyer-Gottlieb and Pick [5] state that the assumption is erroneous that increased excretion of uric acid can be produced by alkalis or by uric acid solvents (piperazine, lysidine, lithium carbonate and so on), as is also the assumption that urate stones in the bladder can be dissolved by these agents. Thus the manufacturers' advertising literature perpetuates an old therapeutic error in the face of evidence to the contrary.

Accordingly, no evidence or authoritative opinion has appeared to date which would warrant altering Hanzlik's conclusion that the use of such urate solvents as piperazine and lysidine, with the hope of obtaining therapeutic effects in gout and related disorders, is inadvisable.

As previously stated, among the alleged indications for the use of Lyxanthine-Astier, in addition to gout, are arthritis, neuritis, gallstones and other conditions in which there is no known disturbance of purine metabolism. The use of a uric acid solvent in these diseases, even if it were effective on body urate, is obviously irrational.

CALCIUM GLUCONATE

Calcium gluconate is an effective preparation of calcium and as such may help supply the normal calcium requirements of the body. However, there is no acceptable evidence for a specific therapeutic value of calcium in arthritis, gallstones and so on. It has been reported by Graber-Duvernay [6] that a series of twelve or more injections of 10 cc. of 10 per cent solution of calcium gluconate, given intravenously at intervals of three or four days, remarkably ameliorated the symptoms of five cases of arthritis. The solution is reported to have been less effective when given intramuscularly, despite the fact that intramuscular injection is an accepted method of administering this compound for the systemic effects of calcium. A verification of the therapeutic results claimed by Graber-Duvernay has not been found in medical literature. It may be noted that the alleged therapeutic effects resulted from intravenous, and not oral, use of the calcium gluconate. This is another case of abuse of intravenous medication, since the systemic effects of calcium are readily obtained by the oral and intramuscular methods. It is pertinent that the Council on Pharmacy and Chemistry does not accept claims of therapeutic value in arthritis for calcium gluconate.

OTHER INGREDIENTS

The other ingredients of Lyxanthine-Astier, namely sodium bicarbonate, tartaric acid, citric acid, powdered sugar and oil of lemon, require no special consideration, as their actions and uses are well understood. The diuretic, antacid and possible cathartic actions of the sodium salts of the organic acids could conceivably produce beneficial eliminative effects, which might impress favorably a susceptible patient. But, of course, the eliminative treatment might be carried too far for his good. Some of these results would be obtained by the use of these simple remedies alone, when indicated, or even by liberal drinking of water alone, without the inconvenience and expense of taking them with the other unnecessary ingredients of Lyxanthine. At the same time there is no good reason to attribute specific antigout effects to these common agents, but the manu-

2. Hanzlik, P. J.: J. Lab. & Clin. Med. **2**: 308 (Feb.) 1917.
3. Haskins, H. D.: The Uric Acid Solvent Powder of Urine After Administration of Piperazin, Lysidin, Lithium Carbonate and Other Alkalis, Arch. Int. Med. **17**: 405 (March) 1916.
4. Ornstein, S.: U. S. Patent 2,008,923, July 23, 1935.
5. Meyer-Gottlieb and Pick: Die experimentelle Pharmakologie, ed. 4, 1933, p. 557.
6. Graber-Duvernay, J.: Lyon méd. **154**: 211 (Sept. 2) 1934.

facturer does not mention this in his advertising. Taken occasionally, these common agents might be of less harm to the patient than the other ingredients. However, there is no justification for medication on the assumption that what might do no harm might sometimes do some good, with the complete oversight of *vix medicatrix naturae*.

Claims for the therapeutic value of the oral use of the constituents of Lyxanthine-Astier in the diseases named in the advertising are based on reports which do not represent convincing evidence. The unsigned and therefore unidentifiable testimonials which appear in the manufacturer's advertising circular are of little satisfactory value as controlled scientific evidence. Consistent with the unfavorable opinion expressed in this report is a recently expressed adverse opinion of the claims for Lyxanthine-Astier.[7]

SUMMARY

1. Lyxanthine-Astier is a polypharmacal mixture of four well known drugs of the therapeutic armamentarium and two less common agents together with flavoring and aromatic ingredients.

2. Of the two uncommon agents, lysidine bitartrate is obsolete and in the opinion of the Council devoid of therapeutic usefulness. The other uncommon ingredient is iodopropanol-sulfonate of sodium, whose actions and uses have not been established by evidence adequate to justify its exploitation as a therapeutic agent.

3. The content of the other more common ingredients, namely calcium gluconate, sodium bicarbonate and the tartaric and citric acids, is sufficiently high to produce the undesirable state of alkalosis if Lyxanthine-Astier should be used continuously and indiscriminately. This undesirable effect is considered possible because of the rather liberal dosage of Lyxanthine-Astier advised by the manufacturer, but especially the higher dosage for so-called "acute attacks." Such usage might actually prove dangerous to susceptible individuals.

4. Satisfactory clinical and experimental evidences of the usefulness of Lyxanthine-Astier, either as the whole mixture or as the ingredients individually, are conspicuous by their absence in support of the manufacturer's therapeutic claims, which concern themselves with gout, arthritis, chronic rheumatism, sciatica, neuralgia and several other chronic disorders.

5. Accordingly, Lyxanthine-Astier has no recognized place in the therapeutic armamentarium, the claims for it being unwarranted and misleading, and its exploitation to the physicians and public is unjustified.

The Council voted that Lyxanthine-Astier be declared not acceptable for New and Nonofficial Remedies because it is a needlessly complex and unscientific mixture of well known substances marketed under a fanciful name with claims that are in the main exaggerated and unwarranted.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ANTIPNEUMOCOCCUS SERUM TYPES IV AND VIII COMBINED (See THE JOURNAL, June 18, 1938, p. 2082, and the Revised Supplement to N. N. R., 1938, p. 18).

E. R. Squibb & Sons, New York.

Concentrated Antipneumococcic Serum, Types IV and VIII-Squibb.—Concentrated antipneumococcic serum, types IV and VIII, is prepared by immunizing horses with intravenous injections of cultures of types IV and VIII pneumococci. When test bleedings show the serum to have reached a sufficient degree of potency for these two types of pneumococci, the horses are bled aseptically and the serum is refined and concentrated by the method described by *Lloyd D. Felton (J. Immunol.* **21**: 357 [Nov.] 1931). The usual sterility and safety tests are made, as required by the regulations of the U. S. Public Health Service, and the potency of the product is expressed in terms of the standard serum for type VIII antibodies as supplied by the National Institute of Health. For type IV antibodies the serum is tested against standard serum, the value of which has been expressed in terms of the unit described by Felton in the *Journal of Infectious Diseases* **37**: 309 (Oct.) 1925. Marketed in vials containing 20,000 and 50,000 units respectively of each type.

Dosage.—At least 100,000 units intravenously within the first four hours after diagnosis has been established.

ANTIPNEUMOCOCCUS SERUM TYPES V AND VII COMBINED (See THE JOURNAL, June 18, 1938, p. 2082, and the Revised Supplement to N. N. R., 1938, p. 18).

E. R. Squibb & Sons, New York.

Concentrated Antipneumococcic Serum, Types V and VII-Squibb.—Concentrated antipneumococcic serum, types V and VII, is prepared by immunizing horses with intravenous injections of cultures of types V and VII pneumococci. When test bleedings show the serums to have reached a sufficient degree of potency for these two types of pneumococci, the horses are bled aseptically and the serum is refined and concentrated by the method described by Lloyd D. Felton (*J. Immunol.* **21**: 357 [Nov.] 1931). The usual sterility and safety tests are made, as required by the regulations of the U. S. Public Health Service, and the potency of the product is expressed in terms of the standard serum for type V and VII antibodies as supplied by the National Institute of Health. Marketed in packages of one vial containing 20,000 units and 50,000 units respectively each of types V and VII.

Dosage.—At least 100,000 units intravenously within the first four hours after diagnosis has been established.

BARBITAL SODIUM-ABBOTT (See New and Nonofficial Remedies, 1938, p. 129).

The following dosage form has been accepted:

Barbital Sodium Tablets, 5 grains.

SUPRARENALIN (See New and Nonofficial Remedies, 1938, page 231).

The following dosage forms have been accepted:

Suprarenalin Solution 1:1,000 in 1 cc. ampules (for hypodermic use).
Suprarenalin Solution 1:1,000 in 10 cc. vials (for hypodermic use).
Suprarenalin Solution 1:1,000 in 1 oz. bottles (for parenteral use).
Suprarenalin Solution 1:10,000 in 1 cc. ampules (for hypodermic use).

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

PIERCE MILL YELLOW CORN MEAL

Manufacturer.—Welfare and Recreational Association of Public Buildings and Grounds, Inc., Washington, D. C.

Description.—Bolted yellow corn meal containing the germ endosperm and a small amount of bran.

Manufacture.—Corn which has been thoroughly cleaned is crushed between millstones operating in a restored grist mill for which an "old type" water wheel provides the power. The stones are run at slow speed, causing only a slight rise in temperature of the grain. The ground corn is passed over a bolting cloth, where most of the bran is discarded. The meal, which is not heat treated during milling, is packed in waxed paper and cardboard cartons which must be stored in a cool dry place to prevent rancidity.

The mill is subject to inspection by government health authorities and by a sanitary officer employed by the association.

Analysis (submitted by manufacturer).—Moisture 10.4%, total solids 89.6%, ash 1.3%, fat (ether extract) 4.5%, protein ($N \times 6.25$) 7.9%, crude fiber 1.8%, carbohydrates other than crude fiber (by difference) 74.1%.

Calories.—3.69 per gram; 105 per ounce.

CRADLE BABY BRAND STRAINED AND SEEDLESS CURRANT AND RASPBERRY JAM

Manufacturer.—Glaser, Crandell Company, Chicago.

Description.—Canned strained jam, prepared from a mixture of currants and red raspberries, sweetened with sucrose. The jam may contain small amounts of added acid and/or pectin.

Manufacture.—Currants and red raspberries from Michigan are handled as described for Cradle Baby Brand Strained and Seedless Grape Jam (THE JOURNAL, April 8, 1939, p. 1343).

Analysis (submitted by manufacturer).—Moisture 31.2%, total solids 68.8%, water-insoluble solids 0.3%, water-soluble solids 68.5%, ash 0.3%, protein ($N \times 6.25$) 0.7%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 66.6%, acidity 0.9%.

Calories.—2.69 per gram; 76 per ounce.

THE CASE OF BRINKLEY VS. FISHBEIN

PROCEEDINGS OF A LIBEL SUIT BASED ON AN ARTICLE PUBLISHED IN *HYGEIA*

(Continued from page 2065)

DEPOSITIONS

There were next introduced in evidence, after considerable discussion, depositions taken in advance of the trial by the attorneys for the American Medical Association.

DEPOSITION OF HORATIUS DEWITT OSBORN

Mr. Matthews, attorney for the American Medical Association, read the deposition of Horatius DeWitt Osborn, employee of the Brinkley Hospital in Little Rock, who testified that he graduated from high school in Fulton, Kan., in 1916 and then attended, for three years, the Kansas College of Medicine and Surgery. He testified also that the fee of $750 is paid sometimes by check, sometimes in cash, and sometimes with a personal note for the balance, sometimes in instalments. He stated also that collateral is accepted in the form of investment certificates or bonds.

TESTIMONY OF ARTHUR S. HUMPHREY

Arthur S. Humphrey stated that he was deputy clerk of the District Court of Geary County, Kansas, and that he had personally taken from the records of the court in Kansas a number of depositions developed in connection with a previous suit of Brinkley vs. Fishbein. Mr. Matthews then introduced into the record some depositions from this suit.

DEPOSITION OF HANS V. CHRISTENSEN

Hans V. Christensen testified that he is the auditor of the Kansas City *Journal Post*, that the Kansas City *Journal Post* had carried a rotogravure supplement relative to Brinkley and had been paid $2,842 for the publication of this supplement for one day.

DEPOSITION OF EVERETT E. ELLISON

This deposition stated that Everett E. Ellison is an advertising man. Mr. Ellison described his conversation with Brinkley relative to the job concerned with the rotogravure supplement in the Kansas City *Journal Post*.

Mr. Matthews then introduced the supplement itself as an exhibit in the case.

ARGUMENT ON INTRODUCTION OF FURTHER DEPOSITIONS

At this point the jury was excused while the Court heard arguments as to the matter of further depositions in the case relating to the previous career of John R. Brinkley in Greenville, S. C., one of the depositions being that of an attorney who represented Brinkley in 1913 and who later testified as to the incidents involved. The Court ruled that the attorney's deposition would not be admissible.

On the other hand, the Court ruled that the testimony of James E. Crawford, inmate of a penitentiary in Oklahoma, who had been associated with Brinkley in Greenville, would be admissible. A number of advertisements which had been circulated in Greenville were offered in evidence and postponed for further consideration.

DEPOSITION OF JAMES E. CRAWFORD

Mr. Matthews then read the deposition of James E. Crawford, who stated that he had first met John R. Brinkley in the spring of 1913 in Chicago at the bar in the Brevoort Hotel. They became casually acquainted while having drinks together, later going to Chattanooga, Tenn., with the plan to form medical offices similar to the one in which Brinkley had been previously employed in Chattanooga, Brinkley stating that he had been employed by Dr. Burke, a physician who specialized in venereal diseases. Crawford stated that he and Brinkley studied the methods of Burke in Chattanooga, remaining there two weeks, and then going to Greenville, S. C. They first looked over the city to see whether or not it would be profitable to establish offices and then located on Main Street over a drugstore on the corner, remaining approximately two months. A sign was made reading "Greenville Electro Medic Doctors." Advertisements were placed in the Greenville papers At the time of their arrival in Greenville they possessed less than $10. A credit account was opened at the drug store to cover the supplies and the rent. Their advertisement stated that they were specializing in venereal and nervous diseases, which they purported to treat with 606 and 914. Actually, the witness said, they didn't use either one. "We used instead a colored solution of distilled water for injections." Brinkley did the injections and Crawford was the business manager. A charge of $25 was made for each injection.

After two months, Brinkley and Crawford departed from Greenville. Crawford stated that the immediate occasion of leaving was pressure on the part of creditors for collection of bills.

At the cross examination Crawford stated the he was at present in the Oklahoma penitentiary for eighteen months for having committed robbery with firearms. He had previously served a term in the Federal Prison in Leavenworth, Kan., for transporting a stolen motor car. The robbery was committed at the Hotel Mayo in Tulsa, Okla.

TESTIMONY FOR THE PLAINTIFF: TESTIMONY OF I. F. INGRAM

I. F. Ingram stated that he was commonly known as Frenchy Ingram. He was a ranchman who had once been a patient of Dr. Brinkley's. At this time the jury was excused from the courtroom, and the attorneys presented arguments concerning the question of admissibility of the testimony of patients. This argument occupies some fifteen pages of the transcript, after which the court ruled that such evidence was inadmissible.

TESTIMONY OF MARSHALL SMITH

Marshall Smith testified that he has lived in Del Rio, Texas, for thirty-four years; that he is in the ice business; that he had read the article in *Hygeia*, having found the magazine on the bureau in a hotel in San Antonio. He stated also that the article was much discussed in Del Rio at the time it appeared.

TESTIMONY OF HERMAN LIPPE

Herman Lippe testified that he had lived in Del Rio, Texas, for seventeen years; that he had read the article in *Hygeia*, having purchased a copy at a newsstand, and that the article was much discussed in Del Rio.

TESTIMONY OF CLARA W. BLETHEN

Clara W. Blethen testified that she is a resident of Minneapolis and that she had read the article in a doctor's office in Minneapolis. On cross examination it was brought out that her son-in-law is a pilot for Brinkley's airplane and has been for about eight years.

TESTIMONY OF R. R. TUMBY

R. R. Tumby testified that he is a resident of Ackerly, Texas, and is pastor of the First Baptist Church, and at various times he has officiated in other cities in Texas. He has known John R. Brinkley since 1936, at which time he was operated on in the Brinkley hospital and the operation was performed without charge. He testified also that the reputation of Dr. Brinkley in various parts of Texas as a prostatic surgeon was good.

TESTIMONY OF A. C. PETERMEYER

A. C. Petermeyer was recalled to the stand by the plaintiff and questioned by Mr. Morriss Sr. He brought with him a

copy of Gray's Anatomy, 23d edition, on page 231 of which is a picture of the testicle. He explained with this illustration, and with the aid of a blackboard, the anatomy of the testis, also describing again the nature of the operation performed on the testis, involving tying off of the efferent tubules. The testimony then proceeded:

Q.—All right, just how does Doctor perform or you perform this operation, then, please, sir? *A.*—A sulcus is located between the head of the epididymis; that is, this space between the testicle and the epididymis, all these ducts converging into this area. If we wish to ligate all of the ducts the suture or the ligature—

Q.—What do you mean by suture or ligature? *A.*—The thread, we use linen, is passed through this sulcus, entirely around all of these ducts.

Q.—In other words, if you are wanting— *A.*—If we wish to produce sterility?

Q.—Yes, sir. *A.*—Yes, sir. If not, the needle is introduced through, not around, but through the approximate center portion of the area, the linen suture is carried through with the needle.

Q.—To tie off approximately half of them? *A.*—To tie off approximately half of the ducts.

Q.—Then it is always more or less, is that it? *A.*—Yes, sir.

Q.—And then it is tied there with this linen cord, is that it? *A.*—That is right.

Q.—Now, Doctor, state whether or not in that way you do have the effect to cut off the secretion through those ducts you do ligate? *A.*—Yes, sir.

Q.—And now what is the particular effect that you are trying to accomplish by that part of the operation, this tying off? *A.*—We are trying to accomplish a balanced condition of the secretions of the testicles.

Q.—Now, what do you mean by a balanced condition? Explain that in detail. *A.*—It has been shown that in early adult life there is a normal physiological balance of the secretions of the testicles. Two secretions have been identified, the male hormone and the female hormone. These secretions have been found in the urine, and in an average, normally conditioned male about 18 units of the male hormone are found in the urine. Studies and work with men in the late forties and early fifties have produced this evidence, that there was a physiologically unbalanced condition of these two hormones, male and female.

Q.—One of the doctors spoke of that yesterday, I believe, or something like that. He said on cross examination that he compared it to a change of life. *A.*—Yes, sir.

Q.—Is that the way you would express it? *A.*—Yes, that is true. Paul Niehans of Switzerland and Elliott Smith of London and Lower, who is with the Crile Clinic in Cleveland, Ohio, have made studies of the testicle with its relation to the prostate gland, and unquestionably they have proven that there is a relationship between the unbalanced condition of the testicular hormones and prostatic hypertrophy.

Q.—You mean representing a change that comes about with age, this change of life you speak of? *A.*—Yes. They have discovered that in men about the age of 50 that 50 to 75 per cent of these individuals have shown a definite decrease in the male hormone in the urine. These men also presented urinary symptoms, frequency of getting up at night, difficulty in emptying their bladders, disturbances in the crotch. They also complained of a lowering of sexual vitality. After their work and studies they concluded that if there is a definite relation between the testicles and prostate and the disturbance with the secretions of the testicle, then there must be some similar way of stopping the growth of the prostate and reducing it in size than by the radical method of taking the prostate gland out entirely, so they concluded that if there was a lacking of male hormones why wouldn't it be beneficial to the patient to give him male hormones. Crile gave his patients inhibin, which is a beef extract made from the beef testis. In his series of treatments he observed a 65 per cent improvement by the giving of the male hormone itself. Another method was used and that was the giving or implantation or transplantation of glandular substances from other animals, including the human. And third was the ligation such as I have described to you on the blackboard. By ligation of all or a portion of these ducts they were able to show by the increased amount of the male hormones that appeared following their operation that they have done something to balance the physiological secretions in the testicle.

Q.—Now, do you mean to even up again the male and female hormones, is that what you mean? *A.*—Yes. The results that they obtained from this work showed by actual work done on the patients that their urinary symptoms began to decrease, that the nervousness associated with the condition, so-called change of life, began to decrease, and that they actually noted a recession or a stoppage of the growth of the prostate gland itself, and in many instances a return of sexual vitality.

Q.—Now, did you bring any of those works with you? *A.*—I have Paul Niehans' article, published February 9, 1936, in the *Lancet*.

At this point argument arose as to the introduction of periodicals and references which had been brought into court by the witnesses, including the writings of Niehans and of Lower. It was the rule of the court that such materials could not be introduced, after which the evidence proceeded:

Q.—Now, Doctor, then go ahead now. You were starting to say what you were trying to accomplish by this ligation, tying off. Go ahead and tell what effect, if any, it has when you do tie off and where it has the effect and why. Explain it in detail. *A.*—The effect of ligation aids to reestablish or balance up the hormones in the testicle. The male hormone has been found to be markedly reduced, while the female hormone remains the same. After the ligature or tying off of these ducts we are aiding the testicle to reestablish a normal balance of the secretions.

Q.—All right. Now, what effect does that have on the prostate? *A.*—It was found that when the male hormone was markedly decreased and the female hormone remained the same that there was a beginning of prostatic hypertrophy with its associated urinary disturbances.

Q.—Now, what do you mean by prostatic hypertrophy? *A.*—Enlargement.

Q.—Swelling or enlargement? *A.*—Swelling or enlargement, yes.

Q.—All right, you say you found when they got out of balance that there is then the hypertrophy or enlargement, there it begins? *A.*—Yes.

Q.—All right, then, Doctor, I will ask you whether or not you know historically and medically whether or not at one time in the history of the profession in this country in bad cases of prostate suffering whether they practiced castration of the individual? *A.*—Yes. Many years ago castration of the male, that is, removing both testicles, was practiced. An examination of those men showed that they had complete atrophy of the prostate gland.

Q.—You mean— *A.*—A complete shrinking up of the gland, that none of the male or female hormones could be identified in the urine, thus proving definitely that there is a relationship between the testicles and the prostate gland. Removing the testicle completely produced severe psychological reactions, aside from the fact that it produced sterility and impotency. So the practice was not carried out very far.

Q.—Now, then, go ahead and tell—go back to what you were trying to do, what does it accomplish with this operation of tying off some of them that you do, if you know? *A.*—The results of the operation show that the urinary symptoms decrease.

Q.—The urinary symptoms? *A.*—Getting up at night to urinate and the frequency and the distress associated with passing the urine went away and there was noted a definite reduction in the size of the prostate gland. This did not occur immediately but within the course of a few months. The prostate gland did not enlarge all of a sudden; the enlargement was gradual. The reduction is likewise gradual.

Q.—Now, Doctor, have you or not had occasion—first kill that. I want to ask another matter. With reference to the removal, the older operation of the removal of that gland or with reference to the operation which we laymen speak of as the reaming operation, the transurethral, clipping it away, taking it out, what is the object to be obtained by science, what is the reason for the removing or cutting away of that gland? *A.*—The purpose of removal of the gland is to relieve the obstruction at the outlet of the bladder.

Q.—Well, now, then, will that have the effect or tend to have the effect to stop—to enable them to empty their bladder freely and stop the pain and irritation incident to urination? *A.*—In many cases.

Q.—Is that then the reason for the removal of that gland? *A.*—Yes, sir.

Q.—Or the reaming of it out, either way? *A.*—Yes.

Q.—And, incidentally, as we go along, then this transurethral or reaming operation, you have many times performed that operation, haven't you, doctor? *A.*—Yes, sir.

Q.—In doing that do you remove the whole gland? *A.*—We remove as much of the gland as possible. In fact, we remove it all down to the capsule. The capsule cannot be removed with the transurethral resection.

Q.—What do you mean by capsule? *A.*—The capsule is a fibrous tissue that surrounds the prostate.

Q.—The bag in which it is held, isn't it? *A.*—Yes.

Q.—It is the lining or bag, you might say, that holds it? *A.*—It is the covering of the prostate, similar to the cover, fibrous capsule, around the tonsil.

Q.—Or somewhat similar to the skin that covers the skin. That is, the tissue that holds it, surrounding it? *A.*—Yes.

Q.—Now, is that removable by the transurethral process? *A.*—The capsule?

Q.—Yes. *A.*—No.

Q.—All right. Now, with reference to the purpose, then, of these operations, you say the purpose is to reduce that enlarged prostate so as to relieve the pressure on the neck of the bladder, is that right? *A.*—That is right.

Q.—All right. Now, how do you accomplish that by the operation that you perform now, this Dr. Brinkley operation we speak of? How do you accomplish that without removing the gland? *A.*—After the secretions or hormones of the testicles are balanced or they become fairly balanced we note that because of the relationship between the testicles, the testis, and these secretions that there is a definite association there with the prostate, and by normalizing or by balancing up this physiological unbalance the prostate gland slowly reduces in size.

Q.—Now, is that sufficient to give the relief necessary? *A.*—It is in a great many cases. If the patient has a complete obstruction at the neck of the bladder because of an enlarged prostate and comes to us with a catheter in the urethra or a large amount of residual urine we perform a transurethral resection because the patient has advanced too far, the hypertrophy has increased too far. The patient needs relief immediately from his urinary obstruction. Then we do a transurethral resection. But in the earlier stages of prostate enlargement, before a large amount of residual urine is found in the bladder, it can be done.

Q.—What do you mean by residual? *A.*—The amount of urine left after the patient voids.

Q.—That is, left after he urinates, you call that the residual? *A.*—Yes, sir. In those cases the ligation operation such as I have described to you on the blackboard will aid in establishing a normal balance of the glandular structures and he will get a slow reduction in the prostate.

Q.—All right. So, now, that is the good you are trying to seek by the operation? *A.*—Yes.

Q.—Does that relieve not only this urinary trouble, but then does that have the effect to relieve the pains that the patient suffers from before that? *A.*—Yes, it does.

Q.—Now, what ailments have you found in your experience flow or follow from these enlarged prostate troubles, what effect does it have physically on the individual or may it have? *A.*—The immediate effect on the urinary tract is that the bladder becomes infected, the urinary bladder sooner or later becomes infected by the urine that stagnates in the bladder.

Q.—Now, infected. What does that do when it gets infected? *A.*—Organisms in the urine, germs in the urine.

Q.—Does it produce soreness? *A.*—Soreness, inflammation, swelling of the mucous membrane or lining of the bladder. The attempts on the part of the bladder to empty itself produce strain; after a while this straining weakens the bladder wall and the muscle fibers tend to separate and allow the interlining of the bladder to bulge through between there and form little pockets in the wall of the bladder. The continuation of urine in the bladder finally leads to the formation of diverticulae. This is a large pouch. Sometimes it assumes the proportion of three and four times the size of the bladder. It is then the kidneys in turn become damaged, and you have hydropyonephrosis, pyelitis and nephritis.

Q.—Now, you are talking about pyelitis—nephritis. Nephritis is Bright's disease? *A.*—Yes, disease of the kidneys.

Q.—What is pyelitis? *A.*—Inflammation or infection of the pelvis of the kidney. The pelvis of the kidney corresponding to a funnel in shape, the small end connecting with the tube that carries the urine from the kidney to the bladder.

Q.—All right. Now, may or may not that produce or does it frequently produce pains in the patient? *A.*—Yes.

Q —Where? A —In the back, especially in the lumbosacral region That is the lower portion of the back, the region of the kidneys and below And pain in the crotch and perineum and pain just above the pubic bone over the bladder region and pain in the prostate region

Q —And, now, may or not that condition spread until it causes rheumatism, or does it often? A —Yes, the absorption of poisons from the urinary tract, from the prostate gland, have often produced rheumatic aches and pains in other parts of the body

Adjournment to afternoon session

Questions by Mr Morriss Sr

Q —Doctor, I believe I had been asking you about what was the manner of this tying off operation to reduce the prostate A —The ligation of the ducts or tubes prevents hormones from escaping into the seminal fluid, and they are forced to be reabsorbed by the little veins in the tunic or lining of the testicle thereby remaining in the circulation

Q —Instead of escaping, you mean? A —Yes, sir

Q —Otherwise the tendency would be to escape in the urine? A —They would be lost and escape through the seminal fluid but they are reabsorbed in the blood stream, and in examining the urine the male and female hormone is recovered in about equal proportions

Q —Balanced, in other words? A —Yes, sir

Q —That results you say, in the reduction? A —Yes, sir, of the prostate

Q —Of the size of the prostate and has a tendency to bring back to normal size the prostate? A —Yes, sir

Q —Now this question, while we are on it How long were you with Dr Brinkley in his performance of those operations before you yourself commonly, or at all did operations, did the same operation? A —Three years

Q —Three years? A —Yes, sir

Q —During that time were you with him constantly and assisting him in his performance of the operations? A —Yes, sir

Q —During that three years, as nearly as you could estimate it, because I don't suppose you know the number, do you, and you haven't looked up that and don't know the number, do you? A —Approximately 1 000

Q —And as nearly as you could state, about how many of those operations, that particular operation, did you see him perform, or in other words, how many times and on how many people did you see him perform that operation within the three years before you did it? A —Several thousand

Q —You mean in all or before you did it yourself? A —Before I did it

Q —What did you mean by the one thousand a minute ago A —That was the number that I did during 1936 and, approximately 1936 and 1937

Q —You misunderstood me on that At any rate you had seen Dr Brinkley perform several thousand of those operations before you performed them without his assistance? A —That is right

Petermeyer stated that he had assisted in operating on some 3,000 cases, and that, following these operations, symptoms of prostatitis appeared to diminish, and that there was actual reduction in the size of the gland He stated also that from 90 to 95 per cent of the patients had returned and had developed improvements, and in all 10 per cent had had no relief He stated also that it was customary to say to patients with advanced cases of enlargement that the simple ligation operation might not bring about relief and that it might be necessary to remove the prostate by transurethral resection He stated that this had been the custom in 5 per cent of the cases

Petermeyer also stated that it was customary to reject all cases in which there was a possibility that the condition was malignant He also said it was customary to take a specimen for purpose of biopsy when there was a question as to malignancy and that such patients, when cancer is found, are told to go elsewhere

He said also that in the hospital there were rectal treatments and hernia treatments, that proctology was in charge of Dr Hilburn and also in charge of Dr Louis Kline and that the results were uniformly good

He also said that some of the patients who had not been able to pay were operated on without pay

Petermeyer also said that white cell counts were made before the solution 1020 was injected, and that it was found that the injection of this solution brought about an increase in the white blood cells, and that this was valuable in overcoming infection He also said he did not know how it brought about this effect

Petermeyer also stated that there were three strengths of hydrochloric acid 1 250, 1 500 and 1 1,000 He stated that patients coming into the hospital remain until they are ready to dismiss them, and that there is no definite time for patients to remain in the institution and that during their stay in the hospital the patients visit freely with one another

Objection was taken by counsel for the American Medical Association to this testimony on the ground that in making this statement the article referred to the practice in Kansas and not to that in Little Rock

Petermeyer testified that in many instances the complete procedure is not carried out on the patient, but that the procedures differ with different patients, also that the charges vary according to the procedures

Petermeyer also stated that he had used the ampules in many instances and that the statements published in the article relative to the ampules were not true He also stated that between twelve and fifteen doctors and between thirty and forty nurses had been associated with Brinkley during the time that he had been associated with him

CROSS EXAMINATION BY MR REYNOLDS

In the cross examination, Mr Reynolds asked Petermeyer whether or not he personally had any faith in the goat gland operation for the purpose of reduction of high blood pressure, and for the purpose of reduction of the size of the prostate The *witness objected to answering the question on the ground that* he had not performed any such operation

Q —I am asking for your opinion, and I will ask that you answer yes or no? A —I am not going to give you my opinion, because the only opinion that I have is the opinion that I obtained from Dr Paul Neihans and Elliott Smith and others who have done gland implantations

Q —I am asking you in your opinion as a medical man a medical student, at least, have you any faith in the transplantation of a goat gland in a human in that method as reducing the size of the prostate? A —I wouldn't answer that question on the grounds that I wouldn't be in a position to

Q —Then, you don't know whether you have any faith or not—do you have any faith in it for reducing high blood pressure? A —I don t know that it has been used for the reduction of high blood pressure

Q —Well, if it has have you any faith in it? A —The high blood pressure is caused by glandular disturbances

Q —I don t want to argue with you—

Mr Morriss Sr —We will have to ask the young gentleman to let the Doctor get a short ways in the answer before he interrupts him

THE COURT —As I understand it, he asked the question 'have you got any faith in the goat gland operation for reducing high blood pressure,' and I wouldn't confine him to a yes or no answer, he could say he did or he didn't, and then he could make his explanation, but the way he started out he didn't start to answer the question "yes', answer the question, and then, if you want, make an explanation, you can do that, and nobody is going to be trapped here, and you can t be trapped you can't trap a man with a yes or no answer

A —State your question again

Q —I want to know if you have any faith in that operation as reducing high blood pressure? A —Indirectly, yes

Q —Have you any faith in it as a treatment for hardening of the arteries? A —I don't know

Q —Have you any faith in it as a means of creating additional energy in man? A —Yes, sir

Q —Have you any faith in its cure for epilepsy? A —No, sir

Q —As a cure for syphilis? A —No, sir

Q —Locomotor ataxia? A —No, sir

Q —As any treatment for prostatitis? A —No, sir, unless it is associated—well, prostatitis and true prostate hypertrophy are two different things

Q —That is true I asked you about the one first, and I want the prostatitis, the inflammation? A —I don't believe so

Q —Dementia praecox? A —Indirectly, yes

Q —Diseases of the stomach, bowels and kidneys in general? A —Perhaps not the stomach and bowels, but the kidneys indirectly and the adrenal glands indirectly

Q —Sterility? A —I don't know

Q —How about sterility caused by mumps? A —Gland implantations wouldn t change that

Q —Now, Doctor, I have enumerated several things over here and suppose we change from the goat gland operation and now consider the operation which you have described and which you call the ligature method, would your answers to any one of those be any different than they were regarding the goat gland operation? A —I don't know as I understand your question

Q —Well, would this ligature operation that you have described in your opinion, have an effective treatment for the high blood pressure that is the ligature operation itself? A —Indirectly

Q —Arteriosclerosis? A —Indirectly

Q —Impotency? A —Yes, sir

Q —It would cure sterility caused by mumps? A —No sir

Q —Epilepsy? A —Indirectly

Q —How about locomotor ataxia? A —No, sir

Q —That is caused by syphilis, isn't it? A —Yes sir

Q —General anemia? A —Yes sir

Q —Would the ligature method have any effect on curing prostatitis? A —I don t know

Q —Well now, you have been working with the prostate gland and don t have any opinion on it? A —Well yes, sir

Q —All right, tell my why? A —Why?

Q —Yes, sir What is there in that ligature process that would be a treatment of any kind for prostatitis? A —All right, with your prostatitis you have your associated hyperplasia of the prostate cells and your ligature method will aid in reduction of that hyperplasia but would have no effect directly on the organs or the infection involved in the prostatitis

Q —You mean to say there is also hyperplasia in prostatitis? A —There is always inflammation and swelling

Q —Not hyperplasia—that is only one type, isn't it, Doctor? A —Hyperplasia, there are several types

Q —You also have hyperplasia when you have the condition you described as prostatitis? A —Yes, sir

Q —You know that isn't right? A —You can have prostatitis without hyperplasia

Q —How about as a treatment for constipation does your ligature affect that? A —It is not a treatment for constipation

Q —Doctor, you have done a considerable amount of research and study since you have testified here Wednesday, haven't you, as regards these urinary organs? A —No, sir

Q —You haven't at all? A —No, sir

Q.—On Wednesday didn't you testify that there were fifteen or twenty of these little efferent ducts between the testes and the epididymis? A.—I did.

Q.—Today you have changed your opinion to twelve to twenty? A.—A man can change his opinion.

Q.—That is all it is—that is all I want to know. You haven't done any particular reading in the field of chemistry since you appeared here, have you? A.—No, sir.

Q.—Didn't you testify Wednesday that 1020 meant a chemical formula of 1,000 parts of water to 1 per cent of hydrochloric acid? A.—No, sir.

Q.—What was it? A.—I told you some of the constituents of the ampule.

Q.—Weren't you asked what 1020 designated and you said it was the chemical formula of 1,000 to 1? A.—Hydrochloric acid?

Q.—Didn't you say that Wednesday? A.—I stated the number of constituents of the ampules, but I made no definite statement as to the percentage that those ampules definitely contained.

Q.—You didn't say anything about 1,000 to 1? A.—Yes, sir.

Q.—And you said the 1020 was a formula indicating that, didn't you? A.—No, sir.

Q.—It can be any percentage and still be 1020? A.—No, sir. Those formulas are made according to a standard formula, and they don't vary.

Q.—Didn't you a few minutes ago say they did vary, and you use sometimes 250 to 1 and sometimes 500 to 1 and sometimes 1,000 to 1? A.—Not in the 1020.

Q.—Isn't that what counsel was asking you about? A.—I don't remember.

Q.—You have a different designation for the other formulas? A.—Yes, sir.

Q.—1020 is always 1,000 to 1? A.—To be positive, I don't know the proportion of hydrochloric acid in the ampules.

Q.—You have those other formulas by different numbers in connection with your work now, do you? A.—Yes, sir.

Q.—Did you have when you were practicing here in Del Rio? A.—Yes, sir.

Q.—Do you know what the proportions are at all of any one of them? A.—No, sir.

Q.—You administered them to the patients yourself? A.—Yes, sir.

Q.—You administered something to the patients that you didn't know what was in it? A.—Yes, sir.

Q.—Do you think that is good practice? A.—There is no doctor who knows exactly what is in the ampule, every ampule that he is introducing into a vein; the formula is not on the ampule.

Q.—You didn't have an idea how much hydrochloric acid was in either one? A.—I had a suspicion about the amount, yes, sir.

Q.—What would determine whether you would use 1,000 to 1 percentage or 200 to 1 percentage? A.—Nothing in particular.

Q.—Just use anything, the handiest one? A.—One to 250 or 1 to 500 strength will bring quicker results than the 1 to 1,000 or the 1 to 1,500 or the 1 to 2,000.

Q.—Why is there any point in ever using the 1 to 1,000, then? A.—Well, that could be a matter of a doctor's opinion.

Q.—Well, why is it— A.—There are occasionally some slight reactions from using a more concentrated solution; I have seen some chills and rigors from giving 1 to 250 or 1 to 500; it seldom occurs with a solution of 1 to 1,000.

Q.—Do you know why that is? A.—Yes, sir.

Q.—Why is it? A.—Because it produces too instantaneous a reaction.

Q.—Yet, it didn't make any difference to you which one you used? A.—I didn't say that.

Q.—Well, tell me what it was you said. I am not trying to trap, you, Doctor, I just want to get at what you did and why you did it? A.—We gave 1 to 250 if the patient could tolerate it, that is when we used the hydrochloric acid in the 1020; but I don't know what the percentage of HCl is.

Q.—Are you sure there is any HCl in it? A.—I believe there is.

Q.—Are you sure? A.—I am not positive.

Q.—As a matter of fact, 1 per cent of HCl to 1,000, why, that isn't much different than distilled water? A.—There is that difference.

Q.—Is there any difference in the specific gravity of the two? A.—I am not a chemist, and I couldn't answer that.

Q.—Did you say the results you claimed to have obtained by injecting this hydrochloric acid solution would be obtainable by distilled water? A.—No, sir.

Q.—Would it be obtainable by the 1,000 to 1 solution? A.—There would be a slight increase of the white cells.

Q.—That wouldn't be from the use of one tube or ampule? A.—Not from 1 to 1,000.

Q.—Six ampules? A.—Yes, sir.

Q.—How much? A.—Increase the white blood cells double that amount.

Q.—Would there be an increase of the white blood cells after you use distilled water? A.—I haven't tried it.

Q.—Have you an opinion? A.—I don't know.

Q.—Now, Doctor, when you testified here on Wednesday were we justified in assuming from your testimony that you meant you ligated a separate duct at any time? A.—No, sir, not any separate duct.

Q.—How do you determine how many of them you are going to tie off? A.—We can't determine exactly; the needle is introduced through the central portion, and we assume that about half of them are ligated.

Q.—You can feel those with your hand? A.—Yes, sir, you can, collectively you can.

Q.—But you can't feel number one and number seven and number nineteen? A.—No, sir.

Q.—You didn't mean to leave that impression Wednesday? A.—We don't call them out by numbers; we know there is an average of fifteen of those ducts there, and if the ligature is thrown completely around it you ligate all of them, and if the needle is passed through the central portion we get about 50 per cent of them.

Q.—Wednesday you testified, didn't you, that the reason you ligated them is because you found nodules in them, that is, when you tied them off you found nodules by feeling? A.—There might be a nodule.

Q.—Didn't you testify that is the reason you tied them off? A.—There might be nodules.

Q.—Answer the question.

Mr. Morriss Sr.:—Now, he said "didn't you testify so and so."

Mr. Reynolds:—I will withdraw it.

Mr. Morriss Sr.:—We deny that.

THE COURT:—He can answer the question.

A.—Yes, sir.

Mr. Reynolds:—I will withdraw it.

Q.—Suppose you find a nodule, one on the extreme end and one on the extreme other end of that group, what about that? A.—Probably would.

Q.—So, if you ever found more than one nodule you would tie up the whole group? A.—Yes sir.

Q.—And that results in sterility? A.—On that particular side.

Q.—Have you ever seen a case where you just found one nodule in that group? A.—Yes, sir.

Q.—Isn't it a fact if there is one there is more? A.—There could be one or more.

Q.—What causes that? A.—Nodules?

Q.—Yes, sir. A.—Infection and stoppage of the duct.

Q.—And it is your opinion that that will usually occur in only one duct at a time and may have no connection with the other ducts? A.—It may occur in one or more ducts.

Q.—Now, how do you determine whether you are going to tie off five of them or eight of them or what? A.—If we find that there is considerable involvement of the epididymis on the first side we ligate all of them, but before the operation is begun we attempt to determine which side is involved the most, and if it is the right side we operate on the right side first, and if it is the left side we try to leave the better side of the two without ligation of all the ducts.

Q.—Now, how large are those ducts? A.—They are about the size of a lead in a pencil.

Q.—Do you know Dr. Folsom who is professor of urology of Baylor in Dallas? A.—Yes, sir.

Q.—Do you know whether or not he is recognized as an authority—

THE COURT:—You can't ask one witness to pass on the credibility of another witness.

Q.—Have you the opinion, Doctor, that you are able to see these ducts by the mere looking at the tissue? A.—No, sir.

Q.—Manipulating them? A.—No, sir; you can't see the ducts individually.

Q.—They squeeze together when you twist them? A.—Yes, sir.

Q.—Yet, you can feel them? A.—In a group.

Q.—You can feel the whole group? A.—Yes, sir.

Q.—You testified Wednesday that in the ordinary operation seven or eight of them were ligated or tied off? A.—Yes, sir.

Q.—Now you mean that that is all in a group? A.—That would be half of the group on one side.

Q.—All right, now, Doctor, does the tying off of all of those produce sterility? A.—Yes, sir.

Q.—Now, sometimes in connection with your ligature operation you tie off all of those, and then go on farther up in this line where the sperm proceeds and you take a section out of the vas deferens? A.—Yes, sir.

Q.—When you take a section of the vas deferens out, that alone produces sterility, doesn't it? A.—Yes, sir.

Q.—When you ligate all of the ducts alone, without touching the vas deferens, that produces sterility? A.—If the ligature is placed around tight enough.

Q.—You always place them tight enough? A.—Yes, sir.

Q.—There is no point in putting it on there loose? A.—I wouldn't think so.

Q.—What, then, is the purpose of taking out a part of the vas deferens tube up here after you have already cut off all of these little ducts down here? A.—When we attempt to inject the mercurochrome in the vas deferens and it is blocked at the point of injection, we draw down on the approximate portion of the vas deferens endeavoring to get above the obstruction in the vas and if we are successful in doing so we inject the mercurochrome, and if we are not, if this vas is full of cheesey pussy material, we remove as much of it as we can clear down to the head of the epididymis because it is an area of infection, the tube is no longer useful to the patient, he is already sterile and blocked.

Q.—If you found that vas wasn't clogged up at all after you tied all of the ducts you wouldn't touch the vas, would you? A.—No, sir.

Q.—Now, Doctor, you were explaining a while ago about tying off these ducts, that it then retained a certain substance in there, and what is that substance? A.—Seminal fluid.

Q.—Is that the only secretion of the testes? A.—Testicular fluid.

Q.—As a matter of fact, there are two different types of secretion, the internal and external secretion, in that organ, aren't there? A.—There are two secretions.

Q.—All right, now, the internal secretion is the one that goes through these little ducts up into the vas and up into the seminal vesicle, or is it the external? A.—Internal.

Q.—Is that the one that contains the hormones? A.—Yes, sir, one of them.

Q.—Does the external also contain hormones? A.—One contains the female and the other the male.

Q.—Which is which? A.—The cells from the interstitial—

Q.—I am asking whether the internal or the external secretion contain the female or the male? A.—The internal contain the female.

Q.—All right, then, when you tie off all of the ducts you are merely preventing the female hormone from getting up into the vas, and, so, according to that— A.—No, sir, you are not; after you—state your question again; perhaps I didn't understand exactly what you meant. Do you mean that this hormone escapes through the seminal fluid to the seminal vesicle or to the blood stream?

Q.—I asked if there is any difference in where the external and the internal secretions escape? A.—The secretions escape through the seminal fluid.

Q.—Both internal and external? A.—I don't know.

At this time the court recessed until the afternoon session.

Questions by Mr. Reynolds:

Q.—Dr. Petermeyer, where in your opinion is the sex hormone introduced into the human body? A.—In the germinal epithelia.

Q.—And that means the testes? A.—Yes, sir.

Q.—And, then, whichever secretion it is that goes through the ducts and goes up into the seminal vesicle and out the body in the usual course, that takes that hormone right along with it? A.—No, sir.

Q.—What happens? A.—It is taken up by the circulation.

Q.—Both male and female? A.—Yes, sir.

Q.—None of them go through the little tubes at all? A.—None of the internal secretions, no, sir.

Q.—None of the hormones? A.—I don't think so.

Q.—Then, why do you tie off the efferent duct in an attempt to keep the hormones in the body if none of them ever went out there in the first place, that is all I want to know? A.—You are not ligating those ducts to keep the hormones in the body, you are ligating the ducts to produce a congestion of the cells so that they can, so to speak, regenerate and start the secretion of male hormone.

Q —In other words, those very cells that used to secrete the part that goes out through them now discharge that duty and start another one, is that it? A —No, sir

Q —They die? A —No, sir There is a regeneration of the epithelium, which produces the hormones

Q —It takes the place of the other one, or what is that regeneration? A —It regenerates the cellular structure

Q —What is produced by the interstitial cells? A —An internal secretion

Q —Containing no hormones? A —Yes, sir

Q —And does it go out through the ducts? A —Through the circulation

Q —Then, you didn't mean to imply this morning at all that you were tying those off for the purpose of preventing the escape of a hormone? A —No sir

Q —You think that tying them off does prevent the escape of a hormone? A —Tying them off does, as I stated before, produce a congestion of the epithelial cells which produce the hormones, and these hormones are absorbed by the circulation and do not pass out through the testicular fluid

Q —There is no idea which hormone is going to be produced, is there, the male or the female? A —Yes, sir

Q —Which produces which? A —You mean which cells produce which?

Q —Yes sir A —The interstitial cells produce the female hormones

Q —And what produces the male? A —The germinal epithelia

Q —Now, the literature you referred to this morning about increasing or decreasing hormones had nothing to do with your operation, did it? A —Yes, sir

Q —Wasn't that literature regarding the injection of a hormone secretion? A —It was regarding three things, the injection of a hormone secretion, the implantation of glandular substances and the ligature operation

Q —Who wrote up that ligature operation? A —Paul Niehans

Q —*Did this man Lower* that you relied on so much— A —Lower made the conclusive statement that 65 per cent of his patients who had received the glandular substances alone responded to treatment

Q —You didn't mean to imply that Lower performed the ligature operation? A —I did not

Q —As a matter of fact the only operation he performed, if any, in that regard is the taking of a section out of the vas deferens? A —I don't know

Q —In that connection Doctor, I will ask you if you didn't the other day when you were on the stand make this answer to the question, which I will read "Question Do you know of any other recognized doctors in the United States that use the technic of operation that you have here described? Answer Yes sir Question Who are they, please?" and then we have this business about you didn't have their consent to divulge their names, and you recall that, and then "Question "—well, the answer was "I do not have the consent to divulge their names, but I can give you one whose article has appeared in literature published by the institution Question By which institution do you mean? Answer From the Crile Clinic in Cleveland Ohio" A —The answers I gave was with reference to the use of glandular extract

Q —The first question there related to this operation, didn't it? A —I don't know whether Lower has experimented—

Q —You didn't mean to tell the jury at all that Lower had ever done this ligature operation and claimed the things for it that you claim, did you? A —I don't remember

Q —Do you mean that now? A —I do not

Q —Now, Doctor, this injection of the hormone extract, upon which you based your opinions before, how was that extract prepared, from what? A —You mean how—it is the extract you are talking about?

Q —I mean what is the substance they use to make a sex hormone or isolate it or get it, or whatever it is? A —Use glandular tissue There are some synthetic hormones that are made without the use of glandular tissue

Q —How are those made? A —I don't know

Q —You don't know whether they are made from urine? A —I have never gone into the chemistry of how those preparations are made

Q —You don't know whether it is possible to make them from urine? A —I believe it is

Q —And why is that? A —I don't know—because they appear there, for one thing

Q —In other words they are taken into the circulatory system and then they get into the bladder? A —Yes, sir

Q —They don't go through the vas deferens? A —No, sir

Q —Doctor, did you mean to imply that Dr Lower agreed—that he advanced the theory that cutting out a section of the vas reduces the size of the prostate? A —I don't know

Q —You didn't mean to imply that at all? A —No, sir

Q —Now, then, this substance that you referred to this morning in *your description* of how and what the sex hormones function is, was inhibin? A —Yes sir

Q —Who was it that wrote about that? A —Lower

Q —And how was that administered? A —Orally, I believe orally, by *mouth*

Q —You didn't say this morning that it was administered by injection into the veins? A —I don't believe so

Q —You were wrong if you did? A —Yes, sir, if I made that statement I was wrong

Q —Have you ever injected it? A —No, sir

Q —Never had an opportunity to observe its effects, then, in any manner? A —Not personally

Q —Now, in *tying off the tubules back there*, again, does that cut off the blood supply to the testes? A —No, sir

Q —Now, Doctor, in the treatments that you give at Dr Brinkley's hospital, or that you give prior to 1938, did I understand you to say that you reject cases where a prostate has cancer? A —If we know it, yes, sir

Q —You don't purport to treat that? A —No sir

Q —You send them to somebody else? A —Yes, sir

Q —*That somebody* else is a doctor there in Little Rock? A —We have told some patients about Dr Marshall's Hospital, yes, sir

Q —Is Dr Marshall an eclectic doctor, if you know? A —He is

Q —Does Dr Marshall have anything to do with the Eclectic Board of Arkansas, if you know? A —I don't know

Q —Now, how is it that you determine that a prostate has cancer when the patient comes to your hospital? A —Examining the prostate with the index finger, and the cancerous prostate often feels nodular with areas of increased density and stoney like hardness and the gland is usually adhered, so much so that it is not movable in the least

Q —*In other* words, you determine it yourself, do you? A —No, sir

Q —Well, the doctor that is doing the operating? A —We usually use *laboratory tests to* determine the tissue we are examining

Q —You have pathologists to determine that? A —Yes sir

Q —Who is that? A —Kirschberg

Q —I thought you said yesterday that he was a licensed laboratory technician? A —He is under Dr Chandler, who is

Q —Is what? A —Head of the laboratory, in charge of the laboratory

Q —Is he a pathologist? A —Yes, sir

Q —Is he a member of the *American Association of Clinical Pathologists*? A —*I don't know.*

Mr Morriss Sr —We object to that as irrelevant and immaterial We have an idea, and you might let us suppose, for instance, that he might be, and at the moment he went with Dr Brinkley they discharged *him from that*

Mr Reynolds —I will withdraw it It is immaterial

Q —Doctor when you were here in Del Rio you yourself attempted to determine by this method that you have described whether a person had a cancered prostate or not? A —No, sir

Q —Do you know anything about cancer? A —Very little

Q —Did you ever attempt to treat a patient that was reported to you to have cancer? A —No, sir

Q —Now, Doctor, previously in your testimony you referred to the Steinach operation, and the Steinach operation doesn't have anything to do with making the sutures in the ligature at all, that you are talking about does it? A —It has to do with the ligature

Q —Not with the ducts? A —Yes, sir

Q —Isn't it a fact that that is merely cutting out a portion of the vas? A —*Not the Steinach No 2*, it is a ligation

Q —*Of what*? A —*The head of the ducts* you are ligating all of the ducts but not the vas deferens, you are ligating the portion of the epididymis known as the head of the epididymis, where all of the ducts end and terminate in the head of the epididymis

Q —It is an entirely different thing from your operation ? A —No, sir

Q —It is the same? A —Yes, sir

Q —And that you identify as the Steinach No 2? A —The Steinach No 2 is where they are all ligated at that point, and we modify that when we ligate only part of them

Q —Now, Doctor, on your direct examination here counsel asked you if patients were allowed to come and go, pay or not pay, as you please to which you answered "yes," and is that the correct answer to that? A —To come and go, and those who aren't able to pay and *can't pay*, some of them don't pay

Q —You generally find out beforehand whether they are going to pay? A —We have no way of knowing what their financial rating is

Q —Isn't that your job now? A —No, sir It was

Q —You quit doing that entirely? A —Yes sir

Q —When did you quit that? A —I haven't done that since I was in Del Rio, I did some of that work when I was here

Q —I thought you had only been the business manager since you were in Del Rio? A —I am in charge of a different line of work in Little Rock than I was here, I am the business manager there where *the charts are kept and where the correspondence is kept*

Q —You did that in Del Rio? A —Yes, sir

Q —And you practiced medicine here, didn't you? A —Yes, sir

Q —You have a license in this state, don't you? A —Yes, sir

Q —Do you have one in Arkansas? A —No sir

Q —Who has taken over the work that you did down here now? A —Dr Osburn and Dr Brinkley

Q —So you haven't got a license in Arkansas? A —No sir

Q —And he hasn't got a license in Texas? A —*I don't think so*

Q —So, when you move you two just switch around, is that it? A —Yes, sir

Q —Now, with regard to your claim that this hydrochloric acid solution may combat infection and increase the white blood *cells, isn't it* a fact that infection itself is often marked by an increase in white blood cells? A —Yes, sir

Q —Now Doctor, referring to the prostatic enlargement where there is difficulty with urination, when you take a *man* in that condition put him in bed for a week and let him get a good *rest* that in itself will somewhat relieve that condition, won't it? A —If it is prostatitis it will

Q —I said prostatic enlargement A —No, sir If it does, it is only temporary

Q —Now, if you put him in bed—well, it will *do* it, though? A —Temporarily he may get some relief

Q —*Now* suppose you take off the urine at the same time, the residual urine, and let him have that week of rest, it has a *more* permanent effect doesn't it? A —It makes the rest in bed more effective when the catheter is introduced and the bladder is depressed slowly, and the—yes sir, he improves from that alone, but the improvement is only temporary

Q —Now, Doctor, can you tell us what is the function of the prostate gland? A —The only function that I know of is that the description that was given was that it is an accessory sexual gland, the secretions of which augment the seminal fluid or add to it

Q —How does the secretion of the prostate gland get to the seminal fluid? A —In the urethra

Q —*In other words* the seminal fluid and the semen *itself never* does go into the prostate gland, does it? A —The seminal *fluid only* goes through the ejaculatory duct

Q —And that goes through the prostate gland? A —Yes, sir, the ejaculatory duct passes through the prostate gland, but the tube just passes through and there is no opening from the ejaculatory *duct into* the prostate gland

Q —That is just like a hole through it? A —Yes, sir

Q —*It doesn't* circulate throughout the gland? A —Yes, sir

Q —And it runs into the urethra by a separate tube? A —Yes sir

Q —And then the prostate gland itself, a little lower down has another tube of the same nature that runs into the urethra? A —There are a number of small ducts

Q —Incidentally, did Dr Brinkley originate what you referred *to as* the injection method of treating hernias? A —No, sir

Q —In fact, that is quite common, isn't it? A —It is

Q —It is nothing *particularly in your specialty* at all? A —No, sir

Q —What percentage of the patients that *come* to you do you *advise* to go somewhere *else*? A —From 5 to 10 per cent

Q —What per cent have cancer? A —I don't know

Q —You mean that *your hospital*—Dr Brinkley advertises over the radio, people come to him for treatment and you tell them *to go some* place else in 10 per cent of the cases? A —I can't give you the number or the percentage of the patients, I don't have that in mind

Q —Isn't it a fact that *20 per cent* of the enlarged prostates are caused by cancer or accompanied by cancer, at least 20 per *cent*? A —I don't know what the percentage is

Q —Well have you an opinion? A —That all depends on the *age of* the patient—

Q.—You don't want to state. If you don't want to state, say so. A.—State the question again.

Q.—I said what percentage of all cases of enlargements is a cancerous enlargement? A.—From, perhaps, 10 to 20 per cent.

Q.—But only 10 per cent you send away—. Now, Doctor, you testified that after a patient has been at your hospital a week, now, he stays around, oh, as many days longer as he can or as is necessary, and isn't it a fact that you charge them $35 a week for that, though? A.—Our hospital charges $35 a week.

Q.—You were with Dr. Brinkley in 1933, and was Dr. Brinkley advertising over the radio then, if you know? A.—I believe he was giving health talks over the radio at that time.

Q.—You call a health talk a talk where he asks patients to come and be treated by him? A.—They are asked to come for an examination—why, yes.

Q.—That is a health talk, in your idea of the word? A.—Yes, sir.

Q.—He was broadcasting at that time over XER? A.—Yes, sir.

Q.—Is he broadcasting over it now? A.—Yes, sir.

Q.—It is a different name now? A.—XERA, I believe.

Q.—Was there any space in there that he didn't broadcast over that station? A.—I believe the station was shut down for repair work, or something, for a while.

Q.—Just for repair work? A.—So far as I know.

Q.—You don't know anything about an effort to take him off of the air at that time? A.—No, sir. I haven't paid much attention to the radio part, and I can't tell you.

Q.—Doctor, do you refer to the broadcasting that Dr. Brinkley continues to do as health talks? A.—Yes, sir, I would. One of the witnesses who sat in this chair yesterday, a specialist from Dallas, said that Dr. Brinkley's health talks had made men of this country prostate conscious, and that they were now going to urologists in earlier stages of the prostate development than they were previously, and, consequently, his business had been markedly improved and increased.

Q.—Where did you get that information? A.—Right in this building yesterday.

Q.—You weren't in the courtroom? A.—No, sir.

Q.—Doctor, in connection with a health talk, is it still a health talk when Dr. Brinkley tells people to send him the names and addresses of two or five people that then are suffering from prostate trouble and who are financially able to attend the Brinkley Hospital?

Mr. Morriss Sr.:—I think that is argumentative and calling for an opinion and conclusion of the witness.

THE COURT:—Sustain the objection.

Q.—You know that Dr. Brinkley does make such broadcasts as that? A.—I believe so.

Q.—And, yet, you tell us that your business doesn't come by mail? A.—The attention of the people is brought to bear by the radio.

Q.—Then the names come into you, and what do you do then? A.—These patients, as a rule, write and want to know of some one who has been to our hospital for treatment.

Q.—We are not on my question. Maybe you didn't understand. Dr. Brinkley advertises for people to send him names of other persons, then those names come in, do they not? A.—Yes, sir.

Q.—You get communications of that kind? A.—Yes, sir.

Q.—People who are supposed to be suffering from some condition that you can treat and who are financially able to come to the Brinkley Hospital? A.—Yes, sir.

Q.—What do you do with those names? A.—We send them one of our booklets.

Q.—Through the mail? A.—Yes, sir.

Q.—Have you got much response from those people? A.—Sometimes.

Q.—Write them letters? A.—If they write to us.

Q.—You say that is one of the effective means of your advertising? A.—It is part of it.

Q.—Well, is the effect—do you get patients from it? A.—Yes, sir.

Q.—And you write follow-up letters if they don't answer the first one, don't you? A.—I don't know about that.

Q.—You are not doing any of that work yourself? A.—No, sir.

Q.—*Have you ever?* A.—I did—no, sir, I never did any of the follow-up work.

Q.—But you know it was done? A.—Yes, sir.

Q.—Did you get many patients from that method? A.—Some.

Q.—Well, was it ten a year? A.—Sir?

Q.—Was it ten a year, or how many? A.—More than that.

Q.—Two hundred—give me some estimate. A.—Well, I don't have *anything to do with that*, so how can I answer your question?

Q.—You did know about that. All I am asking about is what you know. A.—I don't know whether it is a hundred, two hundred or three hundred; anyway, we get patients by that method.

REDIRECT EXAMINATION

By Mr. Morriss Sr.:

Q.—You spoke about the process of tying off with this linen suture; in other words, it is a *linen string*? A.—Yes, sir.

Q.—Call it that? A.—Yes, sir.

Q.—What about the durability of that? I want to inquire about how long does that last? A.—That linen suture remains permanently; it is nonabsorbent.

Q.—It doesn't absorb or decay or rot, or anything like that? A.—No, sir.

Q.—That is a type of linen suture that remains? A.—Yes, sir.

Q.—Now, I want to ask you about—counsel asked you a great many questions about the technical matters there, but regardless of the exact process in which nature does cause it, have you found and is it your definite opinion that this operation that we have spoken of on the prostate, that Dr. Brinkley's hospitals do for the prostate enlargement, is it effective and beneficial to the patient? A.—Yes, sir.

Witness excused.

TESTIMONY OF DR. MORRIS FISHBEIN

Dr. Fishbein was recalled to the stand by the plaintiff and examined by Mr. Morriss Sr.

Examination by Mr. Morriss Sr.:

Q.—When you were on the stand the other day being examined by your counsel, referring to broadcasts by Dr. Brinkley, you were asked "and from what source or sources did you receive that information," and you gave this answer: "from listening to the broadcast of the plaintiff on many occasions, and on one occasion in which the plaintiff said in my own hearing to the people to send him merely a bill with their name on a sheet of paper mentioning the broadcast, but not to describe the symptoms, merely send the *name* on a piece of paper with a bill; in fact, if I can remember the exact words, he didn't have time to go into the symptoms and that he would send a bottle of medicine that would be of help to them," and I will ask you to identify the time when you heard that? A.—It is my recollection that is several years ago.

Q.—How many years ago? A.—I would say some time after coming to Del Rio, I can't fix it within that definite time.

Q.—Some time after coming to Del Rio? A.—Yes, sir. He may have said "send it to the Del Rio Drug Company," I am not positive, but he said he just wanted the name on a sheet of paper and the two dollar bill, and—

Q.—I didn't ask you to make the speech, I am just asking you when it occurred? A.—To my recollection, several years ago.

Q.—You say it was after he moved to Del Rio? A.—To my best recollection.

Q.—Over what station? A.—I believe the same station from Mexico.

Q.—XERA or XER? A.—I believe from Mexico. I don't try to memorize the names of his various stations.

Q.—The one opposite Del Rio? A.—I believe it was the one from Mexico.

Q.—You mean here by Del Rio? A.—That he was using at that time.

Q.—You are not willing to commit yourself to say what year nor what station? A.—Not without being able to verify it.

Q.—Well, are you able to verify it or do you just give your best judgment? A.—It is my recollection, as stated, that it was several years ago *from a station in Mexico.*

Q.—Now, you said you were listening to him on one occasion in which the plaintiff stated "in my own hearing"? A.—Yes, sir, that is right.

Q.—And you were remembering his exact words "he didn't have time to go into the symptoms and that he would send a bottle of medicine that would be of help to them"? A.—I think those were the approximate words.

Q.—You can't remember the year nor the month nor the place, the station over which he was broadcasting, is that right? A.—I wouldn't attempt to fix it that closely.

Q.—Are you going to say still that it was after he came to Del Rio or do you now think, maybe, it wasn't? A.—I feel quite certain it was after he came to Del Rio.

Q.—But you are not entirely certain about that? A.—Yes, sir, quite certain.

Q.—You said you felt certain it was after he came to Del Rio, is that what you are talking about? A.—To the best of my recollection it was *after he came to Del Rio.*

Q.—You are not qualifying that and you won't say positively it was before or after he came to Del Rio? A.—To the best of my recollection it was after—

Q.—By saying "to the best of my recollection" do you mean you are not certain? A.—I am quite certain. I am modifying the word "certain."

Q.—Modifying it? A.—Yes, sir.

Q.—What do you mean by modifying it? A.—One can be relatively certain or absolutely certain.

Q.—What do you mean now? A.—I am not absolutely certain, I am relatively certain.

Q.—You mean by that that you are not positive? A.—Not absolutely positive.

Q.—Not absolutely positive? A.—No, sir.

Q.—But you still say by the proposition that to the best of your recollection the claim you testified to occurred since he came to Del Rio and over the local station across the river, or, at least, it referred to the Del Rio Drug Store? A.—Possibly.

Q.—One of the three? A.—Yes, sir.

TESTIMONY OF DON HOWARD

Don Howard testified that he is a resident of Del Rio, Texas, and a radio announcer with station XERA, across the river from Del Rio in Mexico, and he represents the accounts handled by the International Advertising Agency, and that he has been connected with the station for two and a half years. He is familiar with the broadcasts. He testified that he had not heard Dr. Brinkley say to send him money and he would send *them a pill* or bottle of medicine.

Cross examination by Mr. Brown:

In the cross examination by Mr. Brown, Don Howard testified that the statement used was "my prescriptions are on file at the Del Rio Drug Store." He testified also that Dr. Brinkley offered $500 in prizes and to win this money one had to complete the sentence "I consider Dr. Brinkley the world's foremost prostate specialist because . . ." He stated also that Dr. Brinkley asked for the names of those physically and financially able to come and see him. He stated also that the time on the station was used by the Consolidated Drug Company of Chicago and by the Sterling Insurance Company of Chicago.

In the re-direct examination by Mr. Morriss Sr., Don Howard stated that the prizes were for the completion of the slogan and for sending names of people who might be interested in the Brinkley literature, and that it was done with transcription. In the re-cross examination, the witness stated that Dr. Brinkley comes out on weekends to broadcast and that the rest of the time records are used.

TESTIMONY OF J. O. WELDEN

J. O. Welden testified that he is plant superintendent for station XERA and that he had not heard Dr. Brinkley suggest that the public send him money and he would send medicine.

On cross examination, he stated that the company is owned by the Frontier Broadcasting Company, which is a Mexican company He stated also that he had heard the people told they could buy medicine in the Del Rio Drug Store, among them one for constipation On re-direct examination, he stated that he had not heard such statements for some time, on re-cross examination, he stated that at one time the station had been closed

March 27, 1939

TESTIMONY OF JOHN R BRINKLEY

DIRECT EXAMINATION

Q—Dr Brinkley, you were on the stand the other day, called by the defendant, I believe? *A*—Yes, sir

Q—How old are you, Doctor *A*—Fifty four my next birthday

Q—Where were you born? *A*—I was born in Western North Carolina, Jackson County

Q—Were you reared there? *A*—Yes, sir

Q—And who was your father and what was his business or profession? *A*—My father was Dr John Richard Brinkley, a physician

Q—And did he or not practice there until his death? *A*—Yes, sir, he practiced through that country there beginning before the Civil War and up until the time of his death in 1896

Q—How old then were you when he died? *A*—Ten years of age

Q—Was your mother then living or had she died? *A*—My mother had been dead five years She died in 1891

Q—And with whom did you live after your father's death? *A*—My mother's aunt raised me

Q—And what were the circumstances, Doctor? Were you poor or was there property or without property, poor, what was it? *A*—While father lived we had plenty to eat After my father died why, it was a case of root pig or die, and there wasn't very much soil to root in We were poor

Q—Now, as to the schooling, early schooling, where did you go to school? *A*—I attended the local schools around there near home like the rest of the children, mountain schools

Q—And did you find employment, work? What did you work at first, I mean, aside from around home what did you work at first? *A*—The first employment I ever had to pay me anything was carrying the mail

Q—What work had you done up to that time as a boy? *A*—I had been going to school and working around on the little farm we had there

Q—All right, how old were you then when you went to carrying the mail? *A*—Well, I was only 16 or 17, somewhere around there

Q—And, Doctor, did you in consequent of that or in connection with that get into something else and how, just briefly? *A*—Carrying the mail from the postoffice up there in the mountains down to the railroad station I became acquainted with the railroad agent and was given an opportunity to stay there with him and learn telegraphy and railroad bookkeeping and how to take care of a railroad agency

Q—Well, go on now and just tell us in your own way about how long before you began to study for a medical career? What was your purpose in employment, and through your youth or boyhood what was your aim or purpose or hope in life? *A*—My hope was to be a doctor like my daddy The day he was buried I said to myself that I was going to find some way or other to become a doctor like daddy was That was my aim and my ambition

Q—And— *A*—I might say the only thing open there a fellow could get to do was to teach local schools and teachers salaries were only $15 a month and school only lasted three or four months a year, so teachers' salaries were only about $45 or $60 a year and there was no chance for anybody teaching school to ever get to medical school, and so I thought learning telegraphy would be better There was a boy that learned it and went to Washington and New York and did very well, so I thought learning telegraphy and getting a way to make money to go to medical school was the better for me

Q—Well, without getting into too much detail, did you pursue your work of telegraphy and the Western Union Agency and so forth until you finally got into school and got your schooling? *A*—Yes sir

Q—And would you mind just briefly outlining where all you worked and studied and whether in or out of school, with reference to how you prepared yourself to be a doctor and how long? *A*—I went from Sylva, North Carolina, to Baltimore to see about getting into Johns Hopkins University because that was the only medical school I had ever heard of at that time Going up there I found I did not have enough education to enter the school and I met a man while I was there in Baltimore that had another school there that prepared young men with—for school entrance requirements, and while I didn't stay there and attend the school with him, yet he furnished me with books to read and outlined a plan of study for me and I went on up to New York City and worked in New York City for quite a while for Western Union Then I worked for the Central Railroad in New Jersey, Hoboken, New Jersey During that time I was doing I suppose today what we would call one of these correspondent courses like we have outlined I would go down to Baltimore occasionally and report how I was getting along and be quizzed and first one thing and another I left New York in 1906 because my aunt who raised me was in feeble condition I returned to North Carolina and she died in December of 1906 and was buried and I married and I went to Chicago and got a job with the Western Union Telegraph Company and found out about Bennett Medical College in Chicago and matriculated in Bennett College in June 1908 and worked for Western Union of a night and went to school of a day And the first year I was in school there in Bennett Dr Robert—Dr John Dale Robertson, who was president of the school, established a literary department that he called the Jefferson Park College, I believe it was During our freshman year in Bennett we freshmen that wanted to take literary work outside of our medical work would go over to this Jefferson Park College at 3 o'clock in the afternoon and spend a couple of hours over there in study until 5 I had to leave at 5 o'clock because I had to be down at the Western Union office at 5 30 to go to work, and that is the way my time was occupied the freshman year

Q—All right and how many years did you have there in that college? *A*—I had my freshman and sophomore and my junior year

Q—Then what did you take the other year? In other words the senior year? *A*—My senior year was taken at the Eclectic Medical University in Kansas City, in which I graduated—

Q—I say why didn't you take your senior year there in Bennett? *A*—Because I owed for my tuition It was a common practice for Dr Robertson to allow students to enter school short of money, figuring they would work it out, but he wouldn't let them enter the senior year without paying up, and I couldn't, so I dropped it

Q—Did you later pay the doctor? *A*—Yes, sir, I paid it in 1921

Q—Did you go, then, elsewhere and—by the way, did you get a certificate or something to practice for a while under your three year work? *A*—Yes, sir, I did

Q—Your research and general work you had done? *A*—Yes sir

Q—What was that? *A*—I got, in the state of Tennessee the law there was that undergraduates could take the examination and receive a license to practice in Tennessee without being a graduate physician I took the examination in Tennessee and received an undergraduate license I practiced over in Arkansas for a short time under a permit issued to me by the Arkansas Eclectic Board of Arkansas

Q—Then, Doctor, right at this juncture you heard of the deposition of this man Crawford who said that you went with him down into North Carolina and undertook to practice there—I mean South Carolina Greenville, South Carolina Did you do that? *A*—No not the way the deposition stated

Q—All right, just what is the fact about that? *A*—I was in Chicago Illinois, and went out to Lincoln Park it was a Sunday afternoon and there was a bathing beach out there and a place where you rented suits to go in swimming and I went up to get a ticket and the man told me all the lockers were occupied, but if I would accept a locker occupied by some one else to go ahead, and I said all right

Q—All right, is that the way you met him? *A*—That is where I met him

Q—All right, what happened? *A*—He was from Mississippi and I was from North Carolina and I was up there alone and he was alone and we were always glad to meet somebody from the South, and we got to talking together and I told him about having previously worked for Dr Burke at Knoxville and Chattanooga and that I was going back with Burke and he said he didn't have anything to do and he said he wondered if he could go down and work for Burke And we went down, and that is how he met Burke, who was opening up these offices

Q—Did Burke open up these offices for special work? *A*—Yes, and employed physicians in the offices and treated venereal diseases

Q—All right did you make an arrangement with Burke that took you to South Carolina? *A*—Burke asked me to go down to Greenville South Carolina, and rent the office down there office space and get out advertising They had form advertising, the advertising was all the same for every office They didn't have one kind of advertising for one town and another for another, it was all built up and arranged And I took this advertising down there and placed these ads and run this opening announcement down there for a couple of weeks and Burke promised when I went down there to take charge of the office to send a doctor that was licensed in South Carolina I stayed down there a couple of weeks and got things ready to go and no physician showed up

Q—When did you plan to open the office? *A*—We planned to open on a certain Monday to be open to the public and start doing business treating on Monday and I called Burke up on the telephone and told him there was no doctor down there and that I was going to leave because I was not licensed down there And he didn't send anybody and I simply got on the train and left and Crawford said "if you are going I am not going to stay here,' so I went over to Mississippi—

Q—You heard Burke's statement of the administration of some colored water of some kind? *A*—I didn't practice—

THE COURT—Crawford you mean? You said Burke

Q—Crawford? *A*—I didn't practice at all I didn't administer any colored water, 916 or 606 or anything else

Q—You left before the time that the office was to have—before the physician was to arrive, is that what you mean? *A*—Yes

Q—All right Now, you heard this testimony that was given by Crawford while an inmate in the penitentiary in 1931 or 1932 an inmate of the Oklahoma Penitentiary on these charges of robbery Did you ever see him after that? *A*—I saw James E Crawford he came to see me in Milford, Kansas, during the summer of 1932 while I was a candidate for governor of the State of Kansas

Q—Was he at large then had he gotten out at that time? *A*—He told me he was out

Q—Did he tell you how he got out? *A*—Yes, he related certain circumstances of how he got out of the penitentiary in Oklahoma

Q—What did he say? *A*—He told me that while he was an inmate in the penitentiary at McAlester, Oklahoma, he was called into the warden's office where he met two attorneys who introduced themselves to him and told him they were from the American Medical Association and that they wanted a certain deposition from him that would be injurious to me and if he would give them that deposition they would assist him in getting out of the penitentiary And he said that they gave him a box of cigars and candies and $20 and left and two weeks later they came back with my lawyers and he gave the kind of deposition they wanted

Q—What did he propose to you? *A*—He told me if I would give him $300 he would make another deposition saying the one he gave them was all a lie

Q—What did you tell him? *A*—I told him to get the hell out of my office I told him if he would lie for them he would give a deposition to me and say I had paid him $300 to get a deposition and they would get another from him I wouldn't have anything to do with him

Q—Doctor, now, when did you—when did you begin the active practice of the—of medicine? *A*—I was licensed in Arkansas, passed the state board there in May 1915, and Tennessee in June 1915 I wrote both boards, passed both examinations and practiced for a few weeks in Memphis and a few weeks over in Judsonia Arkansas, for a short while and I was over there at Judsonia Arkansas where the strawberries are supposed to be good and the river got up and flooded all the strawberries and there wasn't going to be any crop and I met a man who told me he thought Kansas was a good state for a fellow to locate in and I went up to Kansas and went to—

Q—Milford? *A*—Well, I first went to Fulton I first went to Fulton Kansas

Q—And then to— *A*—Then to Milford

Q—Yes, sir How long did you practice at Milford Doctor? *A*—After I began the practice of medicine at Milford, Kansas late October 1917, and remained there until 1933

Q—Now during all of that time were you in the active practice of your profession, medicine and surgery? *A*—Yes sir

Q—Did you or not have occasion during that time to pursue your study as a doctor? I mean what did you do, did you work and study? *A*—From time to time I left Milford Kansas, I would get some doctor to come in and take my place and look after my patients while I was away and I would go off a month or two and go to some hospital or clinic and take postgraduate work I went to Chicago two or three times took some

work there, went to New York, visited different hospitals in New York and clinics, saw operations performed and talked with different teachers.

Q.—Did you or not have occasion then to go to Europe in your work or your study? *A.*—Yes, sir, I received an invitation by a cablegram from Dr. Thompson, from Shanghai, China, in the fall of the year 1923. It was right after that—I associated it with that big earthquake that destroyed Yokohama because I know when I arrived at Yokohama the whole thing was in ruins, and Dr. Thompson asked me to come to Shanghai and I went over to Shanghai and did a few—

Q.—Was that intended as a removal or just temporary? *A.*—It was just a call to go over there and do some surgery.

Q.—I see? *A.*—And I got a little money over there from Shanghai—well, to be exact I got about $5,000 paid me about—I was paid about $5,000 for what few operations I did.

Q.—Now, Doctor, at that time had you or not become interested in any particular line of practice? *A.*—Yes, I had been doing the transplantation of glands into people.

Q.—Well, when and how or what time did you get interested in it, particularly in the gland, the human gland treatment and research and study? *A.*—My attention was attracted to glandular study by Professor Sutow. Professor Sutow was professor of physiology at Bennett College, Bennett Medical School, and he used to quite frequently tell we boys that he believed one of the greatest fields ahead of us was a study of the glands of internal secretion because little or nothing was known of them, and one day a professor came or a doctor rather came in and gave a talk. His name was Dr. Hair, and he gave a very enthusiastic talk about the possibility—

Mr. Brown.—Your Honor, we object to going into what some doctor said in his lectures as being hearsay.

Mr. Morriss Sr.—We don't want the details.

A.—I merely meant to say those two instances are what caused me to become more or less interested in the glands of the body. And a very peculiar circumstance happened at Milford, Kansas. I had only been there about two weeks, being a new doctor in town and having a little drug-store that I had opened up there, and different country people would drop into the drug store to meet the new doctor and pay me their respects and tell me they were glad I was there and so forth. This one man came in and got to talking with me about sexual weakness. I told him I didn't know anything that would do him any particular good as to sexual weakness. The conversation continued and we got to talking about why couldn't we take some glands out of an animal and put them into a man. I told him it was biologically impossible. He wanted to know why it was impossible. I told him because you couldn't transplant the glands from a higher order of animal kingdom to a lower or vice versa. He wanted to know how I knew you couldn't, and I told him that was what' I had been taught and I believed it. To make a long story short, he furnished the animal and I transplanted some glands into him, with good results according to his statements to me.

Q.—What was—was it, Doctor—you spoke about him furnishing the animal and you broke off there. Was it of his own volition? Did he insist? *A.*—Yes, he insisted.

Q.—And through what period of time was that and who joined him in his insistence? *A.*—His wife.

Q.—All right, did you or not visit them out there to see and did you or not advise against it and did you— *A.*—Yes, sir, I advised the man not to have it done and he said "you are a surgeon. You can put them in and if they spoil you can take them out."

Q.—Well, that was true, wasn't it? *A.*—Yes, sir.

Q.—Well, all right, did you or not find any results from that operation? *A.*—To me the results were amazing and startling because I expected bad results and disastrous results and instead of that happy results were obtained. The man claimed that he had been sexually dead for sixteen years. His wife verified that statement. A year later I delivered his wife of a fine baby boy, which at least proved that he was fertile, anyhow.

Q.—Did you or not then perform—did you perform any other operations on his own kin? *A.*—A cousin of his, a cousin of his. Of course, the news got around in great fashion, and a cousin of his came to me and asked me to do the same thing on him and I did and he had me to transplant glands into his wife. Then one of their relatives was in the insane hospital in Nebraska. He had been a banker. He was a banker up there, he was a cashier and lost his mind and was placed in an insane institution. They wanted to know from me if I thought glands would do this insane person any good, and I said "Lord God no," and they said "we want you to try it," because he had been a masturbator and "we know it" and they brought him down there, took him out of the institution, and I put those glands into him and that man recovered his mind and today is in charge of one of the biggest banks in Kansas City, Missouri. He came out of the insane asylum in Nebraska and had those glands put in. I published that in an article in a little magazine, and down in Alabama a lady read it. She had a daughter that had been in the insane asylum for ten years in Tuscaloosa, Alabama. She was violently insane at times. When she went to get a permit, she had to get a state permit to get this daughter out of a padded cell, they had to keep her in what is called a padded cell to keep her from doing injury to herself; she was trying all the time to commit suicide. And my wife and I met this lady with her daughter in Memphis, Tennessee, and put her in a drawing room and brought her to Kansas City and over to Milford. I transplanted glands into that young lady. She stayed in my hospital for a month, fully recovered her mental capacity. She didn't want to go home because she felt she was disgraced because of her previous life. She secured a secretarial position in Kansas City, Missouri, and married a physician and today she is healthy and happy and normal. I can go on and recite instances like that one after the other.

Q.—All right, Doctor—by the way, were you a member of the American Medical Association? *A.*—I was a Fellow of the American Medical Association at that time.

Q.—Now, did you or not from your experimentation, your operations, your efforts, your research, did you become convinced that there was benefit in glandular transplantation? *A.*—I did, I thought I had made a wonderful discovery, I thought this was the grandest thing in the world, I wanted the whole world to know about it.

Q.—Well, did you or not refuse to give it to the profession or did you offer it to them? *A.*—I offered it to the profession. I tried to get some of these things published in various medical journals. They very kindly said they couldn't afford to publish them. I wrote letters to doctors in different states telling them about some of the results I had obtained and asking them to come to Milford and let's see if we couldn't get it before the profession. No interest was shown.

Q.—Did you or not continue that effort? Did you or not have doctors there to witness your operations, there and elsewhere? *A.*—Yes, sir, doctors have seen me operate many times in the United States as well as in foreign countries.

Q.—And why, Doctor, did you go to advertising, just tell the jury your own feeling about it? *A.*—My feeling about the matter was that it was something that was too good and too valuable to lay aside and do nothing about it and that the public should know about it, the people should know about it, the people should have the benefit of it.

Q.—Doctor, what per cent of the population of the country are affected by the—by this trouble that you now operate for and such as that, this glandular—that is, the prostate gland? *A.*—I think it is pretty well considered that about 65 per cent of the men past the age of 50 have some involvement of the prostate gland.

Q.—Well, now, then, was it your desire to do something for those men or for the world at large on that question? *A.*—Yes, sir, it was. I was removing prostate glands, I was a general surgeon doing general surgery and was removing prostate glands.

Q.—Now, in your surgery during those years did you do general surgery? *A.*—Yes, sir.

Q.—I mean all kinds of operations? *A.*—That is true.

Q.—Were you or not then through the years at Milford were you or not actively and busily engaged in your practice as a surgeon? *A.*—Yes, sir, I was.

Q.—And as a physician also, but I am speaking particularly about in surgery? A.—Yes, sir, I was doing much surgery.

Q.—During all of that time were you doing study and research work to further qualify and— *A.*—I was doing many experiments, animal experiments, and people that came to me in the beginning that wanted these glands transplanted or thought they would like to have them, since I had found out they wouldn't hurt anybody to put them into them, why, I transplanted glands to people just to see if it would have any effect on all manner and kinds of diseases.

Q.—Was that always, Doctor, with their understanding of what was to be done and that was done? *A.*—Oh, yes, sir.

Q.—And then we had gotten down to, but I don't believe we got over, the matter of your resort to radio? *A.*—I had been called by Harry Chandler, Harry Chandler the owner of the Los Angles *Times* in Los Angeles, California, had read a little article I had written or published in some magazine some place and he asked me to come out there, an old employee at the time was sick. Mr. Chandler wanted me to put these glands into him to see if it would do him any good. While I was there Chandler was having installed KHJ for the *Times*. I think it was the first radio station that was ever put in there in Los Angeles, California. And leaving California and going back to Milford I thought it would be a nice thing to entertain the patients by having a radio station close to the hospital where they could lay in bed and listen in on their ear-phones, and I bought the station and gave lectures over it, talked about various diseases of the human body and did that up until 1929. I never tried to produce any patients over the radio at all, never even made any effort to. I was using the radio up until 1929 to give musical entertainment and medical lectures and medical advice in a general way. In 1929 I began a series of lectures dealing with the diseases of children. I began to receive an enormous amount of mail from people asking me about this thing and that thing and another thing. I couldn't answer it, and the only way it could be answered was to go on the radio and answer a good bulk of it, and in 1929 from answering those letters over the radio, through the radio, patients began to come to me because of radio advertising.

Q.—Well, what was the result there of your work so far as the membership in the American Medical Association was concerned? *A.*—Well, some time after 1917, I don't remember what year it was, why, I just didn't pay any more dues or bother anything more about it.

Q.—And had you or not been able to get their cooperation or hearing with reference to your glandular treatments? *A.*—No, sir. I wrote a letter to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION briefly outlining some observations I had made in transplanting these glands and asked them if they would consider publishing an article for me, and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION replied—I can't give you the exact words, but I can give you the meaning—they said "if we published in our journal every unverified announcement of a cure or treatment why the American Medical Journal instead of being a scientific journal would just be cluttered up with stuff," that is the meaning of it. "We can only publish articles that come to us verified from scientific sources." That was in substance the reply of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Q.—Now, then, you finally discontinued the transplanting of glands of animals, you say. When was that? *A.*—1933.

Q.—Explain your reasons for that? *A.*—Sundry reasons. One reason was that there was a lot of kidding and joking about this gland business. Many patients it was found out in their home community that they had been down to Dr. Brinkley's hospital, they had gone down and got a pair of glands, lots of men's wives were sensitive to the gland work and gradually more and more there was coming out glandular products and glandular preparations of some merit.

Q.—Had you yourself advocated that, advocated the experimentation in glandular products, the benefits of it? *A.*—Well, I recommend the use of glandular products in the treatment of disease.

Q.—All right, go ahead. I interrupted you. *A.*—Well, I don't understand your question.

Q.—You just said that your reasons for discontinuing the transplantation of the goat gland, the animal glands, as you said there was lots of kidding and then these products, glandular products had begun to be on the market. Is that what you said? *A.*—Yes, sir.

Q.—Well, do you mean by that that you were able— *A.*—I felt like by using good glandular products, injecting them into patients, I would probably supplement to a large extent the transplantation of glands, which is naturally a bothersome accessory method of treatment in your hospital, so I came down here to Del Rio, Texas, opened the hospital here in the Roswell Hotel, and have not done any gland transplanting since.

Q.—All right. Now, Doctor, was your work in that line and has your practice been primarily to make money out of it or what has been your feeling about it? *A.*—No, my idea of the whole thing was to try to get something worked out to where we could save from being removed the prostate glands of men. The prostate gland is one of the sex glands, a necessary gland for a man to retain his body in a healthy condition, enjoy normal sexual life and good health. Removing the prostate gland either suprapubically or transurethrally carries with it a certain amount of surgical risk. These prostate cases, many of them they are not good surgical risks. When they come to the hospital they are carrying residual urine, the functioning of the kidneys is down and they don't stand much shock unless you can get the kidney function up. Some of them doesn't come up very good. There is danger of infection, there is danger of hemorrhage, shock and hemorrhage and infection are three factors that all prostate surgeons or urinologists are conscious of in their work.

Q.—Well, now, then, how did you begin your research to try to find a way out of that? *A.*—How my attention was directed to the glands, these glands that I was implanting having any effect on an enlarged prostate or enabling a man to empty his bladder was that a lot of these men that came to see me for a gland transplantation that was all they

wanted, they wanted a gland transplantation for sexual weakness, they didn't want anything else done to them, they just wanted that for sexual weakness Naturally those patients were examined and many had enlarged prostates, many had difficulty in urinating I always had an understanding with those patients that any time that they wanted a gland transplantation repeated or if they sluffed out and didn't take it, as it is called, they could always come back and have the work repeated any time they wanted to Quite a few of those patients drifted back to see me and they would say "Doctor, if you had done as much good for me in the way of helping my sex weakness as you have helping me urinate I would be tickled to death," and that directed my attention to the fact that planting these glands into a man that was having difficulty in urinating that somehow or other the urinary trouble was helped That was the thing that caught my attention first

Q—*And did you make research in that respect in the old country?*
A—What did you say?

Q—Did you make any investigation or research in the old country on your occasions of being over there? *A*—Yes, sir When I made this trip around the world I made a special trip to Saigon, Indo China *I went to Saigon, Indo China,* because nearby was a colony of eunuchs

Q—By eunuch you mean— *A*—A man who has lost either through removal by surgery, accident or otherwise his testicle He is castrated And with the kindness of the French surgeon who was there in charge of the port at Saigon I went out into the interior a ways to a little village where there was an old monastery *I think* the name of the town was Annom, and there was some eunuchs there and the French surgeon gained their permission for me to examine their prostate And I couldn't find they had a prostate any evidence of a prostate That has been confirmed many times by different observers If a man's testicle is removed in youth his prostate gland doesn't even develop, and if in later life his testicles were removed his prostate gland shrunk up, showing there was some relation between the testicles and prostate

Q—Well Doctor, without going into detail did you pursue that research and that study on through the years? *A*—Yes, sir I might say on that same trip I went to Berne, Switzerland, to see Dr Coker of the Coker Clinic there The Coker Clinic there on thyroid diseases is famous the world over The old man that established the clinic the senior Dr Coker, was dead, but his son who had grown up with him in the work was in charge I spent a very pleasant week with him and discussing the enormous amount of thyroid disease in Switzerland, and he was removing thyroid glands—

Q—Where is the thyroid gland? *A*—The thyroid gland is located astride of the windpipe here in your neck And I asked him when he had to take out too much thyroid what did he do, how did he supply the deficiency

Mr Brown—Your honor, we don't object to the investigation, but the conversation is hearsay.

THE COURT—Yes

Q—Say what you did? *A*—I witnessed many transplantings of thyroids into human beings His way was to take a plug out of the shin bone To make that more understandable, he took out the plug like we boys used to plug a watermelon And he would put this in the marrow, and that was his method He was using sheep glands in thyroid deficiencies

Q—Well, now, Doctor, I wanted to get down to the point of your beginning of your operations on the prostate gland To operate for the prostate trouble—I mean had you or not *performed many of the operations* removing the glands and the like, had you done many of those? *A*—Yes, sir, I have performed many

Q—Well, I believe you said your effort or desire was to find a way to avoid the removal, is that right? *A*—Yes indeed, I wanted to avoid removing the prostate if possible, and as I said my attention was brought to the prostate being affected by the transplanting And about that time Steinach made some announcements about ligating the vas deferens

Q—That is the matter we have been hearing about? In other words, tying off? *A*—*No, not at that time*

Q—I mean ligating means tying off the vas deferens, that large tube? *A*—Steinach first advocated a ligature, a linen ligature around the vas deferens, not cutting it out, just tying off its main channel or line Secondly, Steinach came back and said take out a portion of the vas *deferens And his third work had been to ligate these tubes coming* from the testicle that has been under discussion here And I tried some of those Steinach, those ligation operations first I didn't see that they were of any value because that thread around the tube cut it in two and you had a free end of your tube, and I couldn't see it was a very good policy so of my own volition I commenced taking out a section of the vas along with the transplanting and then I started taking out a part of the arteries, the vas deferens artery, tying it off I was doing all sorts of things to try to see what was best to help the prostate working all the time along the line of what improvements could be made in what I was doing that might lower the size of the prostate and make him empty his urine normally

Q—Was that a research and work and experimentation that if successful would be beneficial and useful to society and to mankind? *A*—Yes sir

Q—Well, now I wish you would tell us just a word about that and what your ambition was for it *A*—My ambition has always been to do all the good that I can in all the ways that I can, and I felt like if I could have introduced something to the medical profession, or world in general, that would save men from a dangerous surgical operation or loss of their glands that it was worth any sacrifice or anything that I could do to accomplish it, *and I still feel the same way today*

Q—Well, did you work out this operation to your satisfaction? *A*—Mr Morriss I don't think that any man ever worked out any operation to his satisfaction I don't think we ever work out any treatment to our satisfaction If we did why then progress would stand still

Q—*I don't mean* that, I mean to the point where you thought it was beneficial and fairly successful? *A*—Yes, sir, to the point where it does good and helps patients, yes

Q—And, Doctor, how long now have you been doing that operation? I mean as a specialty not in individual cases or in connection with your other operations, but as a specialty since you came to Del Rio? *A*—The operation that has been under discussion in this courtroom I began doing it a little before and had it worked out, but put it into universal effect when I came down here to Del Rio in 1933

Q—How many times would you say, as near as you can, you have performed that operation, Doctor? *A*—The one that is under discussion here?

Q—Yes, sir *A*—The ligation of the ducts?

Q—Yes, sir *A*—I believe I would be conservative in saying I have performed at least 3,000 of those operations

Q—You are talking about yourself are you? *A*—I am talking about *what I have done myself*

Q—Now, then, did you or not teach your staff, some of the members of it, to perform that *operation with* you and then finally independent of you? *A*—Yes, sir

Q—And under your supervision, then, and in your hospitals how many times do you believe that operation has been performed including *your work and what your staff has* done under your supervision? *A*—At least 5,000 times

Q—Have you had occasion to follow up the investigation keep in touch with those patients to ascertain whether or not—what the results were and whether or not beneficial results were obtained? *A*—Yes sir I make an effort to keep my patients—keep in contact with my patients By way of illustration, last February I mailed a letter to the last known address of every patient I had any record of ever having been in the Brinkley Hospital, inviting them to a reunion to be held at our Country Club Hospital in Little Rock this fall, and from time to time we write our patients, write them friendly letters, letters of friendly information letters of invitation to return for rechecks

Q—Is it a part of your arrangement and your practice that they may and do always return—I mean may return anyway and should return for check ups and such as *that*? *A*—Yes, we consider our annual recheck business on patients, we consider that one of the best protections to patients that can be given because we give them thorough rechecks to see if anything else is wrong with them other than what was at the time they became my patients That way we can advise what structures in *their body are undergoing pathological changes or diseases that may be* beginning to outline and advise medication, diets and care of them In so doing we enable these patients to live longer and healthier and happier and get more out of life than if they were not privileged to get that yearly examination service or examination service any time they wanted to return for it

Q—And have you thus had occasion to make extensive study of the effects, the after effects, the ultimate effects of these operations on your patients? *A* I have

Q—Well, now, without pursuing that any further, what is the effect and in what per cent of cases is it beneficial? *A*—I find that following this operation the patient relates a feeling of well being, he feels more energetic

Mr Brown—We think it is hearsay what the patients told him

Mr Morriss Sr—That is case history

A—We find that their blood pressure in many cases where it was above normal has gone to normal

Mr Brown—We have that objection

THE COURT—Overrule the objection

Mr Brown—Note the exception

A—We give these patients an examination when they enter our hospital and we give them an examination when they check out of the hospital and we note the physical findings both at admission and discharge We find that these patients are able to empty their bladders with less difficulty, in many instances no difficulty at all Of course not all of them, you understand, are well of their prostate trouble or disease or enlargement in a seven day period by any means but their urinary frequency, getting up at night, burning draining dribbling has ceased or greatly ceased In a great many cases their blood pressure is down to normal or greatly reduced their appetite is better, they are eating more, or beginning to have better appearance the sickly pallor or color in their faces is disappearing When they came in the hospital probably they had such pain and misery they couldn't get out of bed couldn't sleep without the use of pain relieving medicines We find them upon discharge not requiring any medicine, the pain having gone sleeping well, feeling well

Q—Well, now, after that how long have you observed them for what length of time have you observed the cases after the operation that you might know what the condition continued to be? *A*—We are reexamining and rechecking on patients as far back as fifteen years who come to us in our hospital We find that those patients continue to have good health

Q—Well, now, those that you have operated on by this operation since you came to Del Rio, I mean this same operation since you came to Del Rio have you had occasion to observe and examine and recheck on those that were operated in 1933 and each successive year? *A*—We are doing that daily, we have recheck patients coming to us every day We are examining former patients daily just the *same as we are* examining new arrivals

Q—Doctor, I believe it has been shown and I assume these patients have come from all over the country? *A*—Yes, sir

Q—Now, do you have a good many of them in this region here? *A*—Oh, I have a large number of *patients in the state of Texas*

Q—I know, but I mean in this western area here, Val Verde and adjoining counties? *A*—Yes, sir, patients in Del Rio and outside of Del Rio, in San Antonio, Uvalde and Eagle Pass and all up, all around here

Q—Well, have you observed any similar effects generally over the country, the effects on your patients over the country have been about the same as those in this region? *A*—Yes, the effects, *the region* or the geography of the country doesn't have anything to do with it

Q—So the effect is uniform regardless of where they come from, is that it? *A*—That is right

Q—Have you told or did you tell the other day, *I don't remember,* what percentage of your patients are materially benefited by the operation, aside from the medical care and examinations you give them—by the operation, what percentage of them do you think? *A*—I don't think we ever have a patient that doesn't receive benefit in one way or another All patients receive a certain amount of benefit in varying degrees Some of these prostate cases they have to be reoperated on All these prostate cases that I do this prostate operation on I don't get a hundred per cent result with that operation, but I do get a very high percentage of results and those that come to us if the prostate does not become reduced or for *some reason they can't* empty their bladder we have them come back to the hospital and we do further surgery on them

Q—Doctor, in your advertising and in the pamphlets and also over the radio, why do you advertise as *plainly as* you do to the public? What are you seeking to do?

Mr Brown—Your honor, we think that calls for a conclusion, just a self serving declaration about what he has been doing and it is immaterial and irrelevant

Mr Morriss Sr—What is his purpose is what I am getting at

Q—Is it your purpose merely to make money for yourself or is your purpose to benefit your fellow man? *A*—My primary aim of course is to benefit sick people

Mr Brown—*Your honor,* I think that is clearly objectionable

THE COURT—Well, this examination is taking rather a wide range and the Doctor has been allowed without objection to express a good many conclusions and opinions and generally give his version of the matter

He was interrogated the other day fully from the defendant's standpoint of it, and I think I will let him state his views with regard to his opinions or conclusions. Of course, they are not binding on the jury any more than *Dr. Fishbein's* were.

Mr. Brown:—We except to the ruling of the court.

Q.—Just state what has been your aim and purpose in it all, Doctor? *A.*—My aim and purpose as previously stated primarily is of course to reach the sick people and benefit sick people. Naturally in advertising and maintaining expensive institutions, buying radio time, money must be had, we must charge for our services; poor people are coming to us, many people coming to us not able to pay are operated on free of charge. We operate on many physicians without charging them anything. We operate on many ministers without charging them anything. We operate on many men and women for fees like $25 and $50 and $75 fees in fact sometime. Our examination fee being $50 for the kind of examination we give. We even sometimes go ahead and do the examination and all the person can pay is $50 for the examination and we give them additional treatment without additional pay.

Q.—Doctor, I am not going to go through the details of this article with you. You have read it and we have inquired about, for instance, these various statements about patients coming in on Monday and leaving on Friday and not letting the next week's patients know what was done. What about that, have you ever tried to conceal the facts from your patients? *A.*—Absolutely not. My patients mix and mingle and visit with one another, take down one anothers names and addresses and get back home and correspond with one another. We have reception rooms, entertainment rooms, play rooms. The patients mix and mingle together. The patients are coming in every day and leaving every day.

Q.—Has that always been the case, have you always permitted and encouraged them to mix and mingle? *A.*—Our patients have always mixed and mingled together without any restraint on our part or any influence or any suggestion on our part.

Q.—Doctor, they spoke of your licenses having been revoked in places. Now, let's see. Did you ever go and study in Italy and get a license there? *A.*—Yes, sir, I went to the Royal University of Pavia, Italy, took the final examination and received the degree of Doctor of Surgery in June of 1925; returned to Italy in November of the same year and took the nation or state examination which was necessary and passed and became a licensed and registered physician in the Kingdom of Italy.

Q.—And then did you also pass examination in England and obtain a license there or right to practice? *A.*—It was not necessary to pass an examination in London, the Italian license that I had, the Italian examination was considered the equivalent of the English examination and on the basis of the examination I passed in Italy I was immediately registered to practice in the Kingdom of Great Britain and her possessions.

Q.—Doctor, do you know whether or not the American Medical Association or its members or officers assailed you in reference to those matters and those rights? *A.*—*Yes, I know.*

Mr. Brown:—That would be hearsay unless he had some evidence of it, your honor.

A.—I graduated—

THE COURT:—Just a moment. I don't see the materiality of it, as to this defendant here.

Mr. Morriss Sr.:—Well.

Q.—Doctor, were those licenses to practice in England and Italy later withdrawn? *A.*—Yes, sir.

Q.—And they spoke about some licenses in some of the states of the United States where you had gotten licenses having been withdrawn or revoked. Was that done around in the same general period? Was it done after your withdrawal from the American Medical Association and your beginning to advertise? *A.*—Yes. The Connecticut license was revoked in 1923 while I was in China. The Kansas license was revoked in 1930 while I was in Kansas. The English license and the cancellation of the Italian degree I thought occurred in 1927. I am not sure of the year, it might have been 1928.

Q.—Well, I believe you said the other day that the Connecticut license, that there was a large number, wasn't it, that was a large number of licenses? *A.*—In Connecticut?

Q.—Of many people? *A.*—That was a blanket revocation in Connecticut, every Eclectic doctor, I think, so far as I know, had his license revoked automatically.

Q.—What are and have been the various—what we call schools of medicine? I mean by that the different denominations or the names of the different ideas or branches such as surgery and allopathical and homeopathic and eclectic, *is that all?* *A.*—Pertaining to medicine I believe those three schools, the eclectic, homeopathic and allopathic were the schools pertaining to the use of drugs. There is the chiropractic institution and the osteopathic institution which started out, I believe, to practice manipulation and massage. I think now they have gone into the practice of medicine.

Q.—You spoke about your license being revoked out in California or an indictment—or an indictment preferred out there? *A.*—Yes, sir.

Q.—Now, just tell the jury about that? *A.*—All I can tell you about it is Mr. Chandler wrote me asking me to come to Los Angeles, California, and operate on his editor. I replied to Mr. Chandler that I was not licensed in California and he conferred with the secretary of the California Medical Board, Dr. Pinçum—

THE COURT:—Now, that is bound to be hearsay, Doctor.

Q.—Were you advised— *A.*—I was called out there. What I was trying to get at, I was called in consultation by another physician in California to come out there in consultation with him on this patient that Chandler wanted me to operate on, because under the medical practice acts if I am licensed in Texas and a licensed physician in Illinois calls me up there in consultation on a case or cases I violate no practice act by going to Illinois with this physician that is licensed there, *providing I am licensed here.* It is not necessary for me to get a license. And it was under that arrangement I went to California, stayed out there I think six weeks, there was some kind of permit issued, I don't remember what it was, some kind of permit given for me to remain there and do some work for thirty days. Later on there was an indictment returned against me and I read the allegation in the governor's office in Topeka, Kansas, in which it said I had been—

Q.—You need not—well, was it for violating—practicing out of authority? *A.*—Violating the medical practice act of the State of California, as I understand it, remember it.

Q.—All right, was that later—was that indictment dismissed? *A.*—The charges were dismissed, yes, sir.

Q.—You were asked the other day if you weren't convicted of a liquor charge. Will you just tell what did happen about that, Doctor, exactly? *A.*—One of my patients at Milford, Kansas, or near Milford, Kansas, a little town called Elyria, was a dentist and he was opening up his office in Wichita, Kansas. He came by to tell me goodbye and asked me if I would give him a bottle of alcohol to use in his office down there until such time as he could get a permit or make arrangements to get his supply of alcohol he would need in his office in Wichita. And I was very glad to accommodate him and wrote a note to my wife who was down at the drugstore, I was up at the hospital, wrote a note to give the man, the doctor, a pint of alcohol, and she did. He went down to Junction City, which was 12 miles from us, met some of his friends there, proceeded to drink the alcohol and he got gloriously drunk. Kansas has a bone dry law, they could arrest you for smelling breath on your liquor—I mean liquor on your breath.

Q.—Was that the charge, Doctor? Was that what the charge grew out of? *A.*—That is what it was.

THE COURT:—I am not sure that I understand it. As far as he ever got was when they arrested the man that had the alcohol. Why arrest him? He stopped in the middle.

Q.—I mean is that why they preferred charges against you? *A.*—The man was taken to jail in a drunken condition and when he got sober enough to talk they asked him where he got his alcohol and he said he got his alcohol from Mrs. Brinkley up at Milford. I had gone, happened to have left during this time he come to see me in the morning and I went to Kansas City in the afternoon. The county attorney 'phoned me and told me the circumstances and he said "I have to take legal action, Doctor, which to me is regrettable," and I said "all right, take it out on me and leave Mrs. Brinkley alone because I authorized her to dispense that alcohol to that dentist." So the liquor law up there was applied against me. I pleaded guilty to the charge and was sentenced to three months in jail and a $300 fine. The county commissioners said they wouldn't have me in jail because I eat too good, it would cost too much to feed me, and they let me pay the fine.

Q.—*Did you just pay the fine?* *A.*—That is all.

Q.—Doctor, with reference to this charge here, now, you will remember what the article says about your telling people to send their bill—their dollar and get their pill. And you heard what Dr. Fishbein said with reference to what he had heard you say on the radio. Will you just tell us about that? *A.*—I don't make that kind of broadcast. Never at any time do I tell somebody to wrap up a bill and send some money in an envelope minus symptoms or anything and I will send some medicine. I tell people I don't treat them by mail, I don't treat them by correspondence. Night after night in my broadcasts, there is hardly a broadcast goes by I don't say "don't write to me for home treatments, we don't treat people until they come to the hospital and have an examination." Possibly after the examination is completed we find conditions whereby we can prescribe and you can go on home, but we are not going to treat anybody until we have had them in the hospital and examined them.

Q.—This treating by remote control, it states "we treat people by remote control." I don't know where it was, but you remember the statement prescribe by remote control. Is there any truth in that? *A.*—No, I don't do any such thing as that.

Q.—Doctor, you have heard the description of the prostatic operation as given by Dr. Petermeyer. Do you want to add anything to that? *A.*—I could give a whole lot better description and probably more understandable than has been given of that operation, but I hate to take the time of the Court. I think it has been admitted that some kind of operation is performed on my patients, and I am content to let it stand at that.

Q.—In the main, without details, is that the operation, the ligating as Doctor has explained it? *A.*—That is in the main the way that we are treating and operating on our patients now and have been since 1933.

Q.—Now, you have heard the testimony. Did you ever claim that you ligated one duct at a time or anything of that kind? *A.*—Oh, no.

Q.—Doctor, you have heard what was testified by the experts with reference to the physiological impossibility of the operation benefiting people and so forth. What have you got to say about that? *A.*—I know it does benefit people. When a man has been practicing something for more than twenty years like I have, like I have with thousands of patients, examining those patients when they come to see me the first time and seeing them down through the years, seeing the changes that takes place by physical examinations and scientific examinations and knowing that those patients have been benefited, why, there isn't any question about the people being helped. I have two hospitals filled throughout with patients all the time. They wouldn't be coming to me all the time spending their money if they weren't getting something for it.

Q.—You heard the testimony with reference to these vials of liquid. What do you call them ampules? *A.*—Ampules, *yes, sir.*

Q.—All right, do you want to add anything to what Dr. Petermeyer said about that? Do you ever fool the people with just giving them something that doesn't amount to anything? *A.*—Not by any means whatever.

Q.—Or is there a purpose in it? *A.*—When my attention was first attracted to the use of hydrochloric acid in the treatment of infectious diseases and treatment of gonorrhea and syphilis, I read an article by a man by the name of Ferguson, and I took several patients and examined the blood of the patients before I gave them anything and after examining their blood and making findings and recording it I began giving them a series of injections of hydrochloric acid. I gave it in various strengths, some strengths of 1 in 2,000, 1 in 1,000, 1 in 500, 1 in 250 and after using these various strengths on many many patients, watching, observing the reactions and benefits, if any, that would be observed, I came to the conclusion that the safest way to administer hydrochloric acid was in a strength of one in a thousand. I also use it for wet dressings. I use it in combination and conjunction with other medicines.

Q.—Now, will you explain what it is designed to do, what the purpose is of the hydrochloric acid in the solution? *A.*—My observation of it is that it increases the number of white blood corpuscles. The white blood corpuscles are the ones in our blood stream that attack invading organism, so-called disease germs. And naturally the normal patient should have seven thousand white blood corpuscles, and if you increase those by the injection of this medicine to thirty or forty thousand you have a lot more soldiers on your side fighting the invading disease organisms.

Q.—Well, now, then, is there inflammation, infection, around the parts, the bladder and so forth, in these cases? Does that have any effect on that? *A.*—My observation is that it helps these old cystic cases. These prostate cases coming to us, the bladder walls are infected, they have a cystitis, meaning a burning. My observation is intravenous injections of hydrochloric acid aids us materially with the other treatments we give these patients in overcoming and shortening the time of overcoming that particular infection. Also that the administration of

hydrochloric acid materially reduces the healing time in our work on the scrotum and also on the rectum And I find it assists and aids in the healing of old sores on the patient's body In other words, I find it quite a useful drug in my practice Hydrochloric acid is a natural body acid The human stomach contains it

At this time there was considerable debate on the admission of certain evidence into the case, after which the testimony proceeded·

Q —Doctor, in how many jurisdictions are you now licensed to practice and have you been in recent years? A.—I hold a license to practice medicine and surgery in the state of Texas, the state of Arkansas, the state of Missouri, the state of Tennessee, and I still retain my license to practice in the Kingdom of Italy because of a written examination I took before the Italian Board in December 1925

Q —Then, it wasn't the license to practice medicine but the medical degree, is that what it was that was revoked? A —That is true

Q —In Italy? A —That is true, the degree I received from the university was annulled, but the license that I received to practice medicine has never been revoked or canceled

Q —Doctor, concerning your medical research, what have you had and what do you have in the way of a library? I am not talking now about the general equipment in your hospital, but the library, what do you maintain and what do you have in the way of a medical library? A —I have a good, well stocked library of various text books on surgery, practice of medicine, and different diseases, and, year by year, as new publications come out I purchase them, and I subscribe to various medical publications to read and keep informed of what is going on and being done in scientific medicine

CROSS EXAMINATION

By Mr. Reynolds·

Q —Dr Brinkley, referring to this 1020 preparation, 1020 as I understand your testimony of the other day, means 1,000 parts of distilled water to 1 part of hydrochloric acid in a 20 cc ampule, is that correct? A —Yes, sir

Q —Plus the coloring material? A —Yes, sir, that is it

Q —You say you experimented with various concentrations with the strength of this hydrochloric acid solution, and what was the most concentrated solution you experimented with? A —One in 200

Q —And the weakest was 1 in 2,000? A —Yes, sir

Q —And you performed the experiments yourself? A —I had them given under my direction, I selected a group of patients and set them aside in the hospital, and I had their blood examined and then made the record of the blood findings

Q —When was it that you did all of this? A —We did this at one time in Milford, Kansas, and, maybe, more than once, and we did it again two or three times down here in Del Rio, Texas

Q —I suppose Dr Petermeyer assisted you in some of them, did he? A —No, sir, I don't remember that he did, maybe he did, but I don't know

Q —Well, now, Dr Brinkley, who determined which one you were going to use at the particular time? A —I don't understand your question

Q —I mean who was the one to say "we are going to try 250 on this patient and 500 on this patient"? A —I was the one that said that I would want to try 250 on a certain number of patients and 500 on a certain other number of patients

Q —Now, Dr Brinkley, in this substance, this solution, who made that for you, who prepared it? A —I have it made by the Glosser Laboratories in New York City

Q —You order all of these *different concentrations from them*? A —No sir I don't think that I had the 250 s and the 500's from Glosser, I think I secured them from other sources

Q —Did you make any up yourself? A —No, sir, I didn't make any myself

Q —Not any in your hospital were made up by your employees? A —No, sir

Q —Can you tell whether the thousand to one or the 250 to 1 is by weight or volume? A —It was whatever was supplied to me, if I wrote to a manufacturer to give me a given number of ampules and they came to me labeled as such, I accepted them as such

Q —By weight or volume? A —I don't know

Q —Do you know which you asked for? A —I don't know that there is any distinction

Q —Don't you know there is a great difference in the concentration by weight and by volume? A —I left that to the reliable manufacturer, *not being a chemist* and having nothing to do with chemical work, I deal with reliable concerns that put out dependable products in a safe way and that will not be harmful to humans

Q —Those concerns send you what you order? A —I write an order and I say "please send me one hundred ampules of one to five hundred hydrochloric acid and one to two hundred fifty hydrochloric acid and one to one thousand"

Q —And the chemist doesn't know whether you want it by weight or volume? A —I don't suppose he does

Q —You think that is good practice, Doctor? A —Well, I left it to the chemist to send me a product that wouldn't be injurious to the patient

Q —Something that wouldn't hurt anybody? A —Something that wouldn't injure, of course, I wouldn't want to give anybody anything that would hurt them

Q —Doesn't it make a difference as to whether you administer it where you put it and what part of the body you put it in? A —All of these products are used intravenously

Q —You never injected it intramuscularly? A —Hydrochloric acid?

Q —Yes, sir A —No, sir

Q —Doctor, do you remember when your deposition was taken in connection with the case brought against the American Medical Association by Paul Fernel, a Chicago plastic surgeon, out at your home here? A —Yes, sir, I remember giving a deposition out there

Q —In 1937, wasn't it? A —Yes, sir

Q —At that time didn't you testify in that deposition that this 1020 was administered in the muscles? A —If I did it was misinterpreted, and I didn't intend to

Q —If you did you were wrong about it? A —I was wrong if I said so, yes, sir.

Q —All right, now, Doctor, as a medical man administering drugs and solutions and the hydrochloric acid to your patients, you can't deny that there is a great difference as to whether a concentration is by weight or volume? A —Naturally, there is a difference

Q —*How* was that difference determined? A —I don't know It was determined by the chemists

Q —What is the difference? A —I don't know

Q —How do you know there is a difference? A —Well, because the statement is different, one is the *weighing of the product and the other* is to the volume of the product, so, naturally, it makes a difference

Q —*Do you know* whether in preparing a solution to administer to your patient you can use weight as to one ingredient and volume as to another? A —I *think* it would be by weight, I believe it would be by weight, that is my opinion of it

Q —Can you mix them up one by volume and weight by *the other*? A —Hydrochloric acid is a liquid and water is a liquid, and hydrochloric acid mixes with water—I don't see why you couldn't mix it

Q —Could you mix a definite amount of hydrochloric acid expressed in terms of weight with a definite amount of water expressed in terms of volume? A —I would suppose so

Q —It sounds possible, doesn't it? A —Yes, sir

Q —And you know, as a matter of fact, that is often done in preparing medical solutions, don't you? A —It may be

Q —You know, as a matter of fact it is often all by weight and all by volume? A —I never go into the manufacturing of these solutions

Q —Then, 1 to 500, you expect to get the same thing any time whether you designate it, what it is, or not? A —I would expect if I was dealing with some reliable manufacturer that is dependent and supplies the medical profession with products for the administration of their patients, I expect to get a product from them that would be nonninjurious to give a patient

Q —Without telling them in what way it is to be administered and without telling them for what purpose? A —I tell them it is to be given intravenously, but you don't tell for what purpose

Q —I will ask you in connection with this deposition in the Fernel case if you weren't asked this question and if you didn't give the following answer

"Q —That is what I thought too I thought, perhaps, it pertained to that particular function of the body that you were talking about? A —No, sir

"Q —That is the distinction you want to make? This 1020 you have that you use, you inject it in the veins sometimes? A —No sir I imagine the injection of that would be so painful that he might hit me with a ball bat"

Weren't those the questions and answers you gave at that time? A —I can't imagine any such being given, I certainly would never think of such a thing

Q —Dr. Brinkley, after that deposition was transcribed you read that over and affixed your signature, didn't you? A —No, sir, I didn't read it over, I just glanced through it and signed it, and I didn't have time to thoroughly read it or correct it

Q —You don't think the report was right, then, is that right? A —I know I never intended to say any such thing as that, I can assure you that

Q —Doctor, that is your signature there, isn't it (showing witness instrument)? A —Yes, sir, I think it is

Q —Now, Doctor, are there any other types of medicine you administer to patients that you just send an order and a blanket designation of 1 to 500 and you don't tell the chemists it is by weight or by volume for the mixture of those? A —We use many preparations intravenously that we order direct from the manufacturers

Q —Are they standard preparations used by other members of the medical profession? A —Many are

Q —Then, they would know what to do with that, in a general way? A —Yes, sir, and if I write to them and order something and tell what purpose I want to use it for and how I want to use it, they make up a safe and dependable and reliable solution for me

Q —Then, hydrochloric acid is something that isn't generally used, that is something different? A —I think many people use hydrochloric acid

Q —And you think the chemist is fully qualified to tell you what you should use? A —I *think so*

Q —And that you are qualified to use it without knowing whether it contains that percentage by weight or volume? A —*I think a reliable* manufacturer sends you a product that he is supplying to you and other members of the profession that is not any risk being taken in

Q —In other words, the chemical manufacturer is determining the treatment to your patients rather than you, isn't that right? A —No sir

Q —All right, now, Doctor, in using this hydrochloric acid in the blood stream it is a fact that hydrochloric acid is an inflammatory or infection inciting substance, isn't it, that is, causes it, in other words? A —You mean hydrochloric acid would cause infection?

Q —*Sure*? A —I don't think so

Q —How about inflammation? A —I don't think it *would, because* any—in other words, if it was injected inside a vein, the blood stream—

Q —What does it do? A —It has an action that stimulates the production of white blood cells

Q —All right, you tell us how white blood cells are produced in the human body and generally for what purpose? A —They are defensive in their action

Q —In other words, they are produced to combat infection? A —That is right

Q —And when you inject the hydrochloric solution you *don't think* that *there is any infection* goes along with that because of that production of white blood cells? A —No, sir, there is *no infection*, if there was any infection in it your blood cells, why, it would be injuring your patient

Q —I *want to know* how 1020 produced the white blood cells? A —It evidently stimulates the thing that makes them

Q —*It does*? A —That is *what it causes*, and we don't know what causes it, but something goes wrong with it

Q —Is there anything else you give? A —We *inject* in the patient various vaccines and serums to stimulate the human forces and body against the diseases

Q.—And those, you know, are infection inciting substances themselves? *A.*—Those vaccines have been subjected to the heat to a point where the infection has been destroyed and the toxin from the infection is retained, but the organisms themselves are killed.

Q.—Is that your understanding of the vaccination? *A.*—The bacteria is killed.

Q.—Is it true that you inject the vaccine into the body in order to produce the situation that is opposite, but, at the same time, it is one infection that throws off; in other words— *A.*—I think it produces the opposite result, sure, but the vaccine, naturally, is introduced to stimulate the increase of the defensive organisms of the body.

Q.—Doctor, will you tell us where and how white blood cells are produced? *A.*—It is not generally known where the white blood cells are produced; the spleen is one place where they are considered to be made. They increase after taking these ampules.

Q.—Then, Doctor, you say that your work here with 1020 is quite experimental, don't you? *A.*—No, sir, I don't think it is experimental in the way of helping people.

Q.—It is experimental so far as you knowing what is in the substance and knowing where it happens or why it happens? *A.*—I don't think anybody knows what happens or takes place; when we administer many preparations we observe the clinical results and draw our conclusions from what happens after we do something.

Q.—And this 1020 business—Doctor, have you ever tried injecting pure distilled water in place of hydrochloric acid? *A.*—No, sir, I never have.

Q.—As a matter of fact, if you think over your theory very well, Doctor, you know you would get the same result? *A.*—I don't know what result you would get by injecting pure distilled water; I have never tried it or made the observation.

Q.—How much does the 1020 ampule cost you—you say eighteen cents apiece? *A.*—I think something like that.

Q.—And you administer about a half a dozen of them to a patient over a period of a week, you say? *A.*—Seven to fourteen.

Q.—And for that week's treatment, the administration of those seven to fourteen ampules, you charge a $100, isn't that true, Doctor? *A.*—No, sir, not in that way, no, sir.

Q.—What way is it? *A.*—We give those ampules and then we give the patient other medication; that isn't the only medicine we give them.

Q.—When he leaves the hospital do you give him medicine to take home with him? *A.*—We have various prescriptions filled for the patients to take back home and take after they get home.

Q.—Most of them take 1020 if they leave before the postoperative treatment? *A.*—No, sir.

Q.—None do? *A.*—No, sir, not now, and we haven't in two or three years.

Q.—You did then? *A.*—Yes, sir, years ago.

Q.—And your charge was the same whether they stayed for the postoperative treatment or went home, it was still $100? *A.*—No, sir, not based on $100 a man; a man might come and pay $275 for an operation, and the operation and treatments might be $750.

Q.—And it might be $1,500 for the treatment for the payment on an automobile? *A.*—It may not be on an automobile. When the patient gets home, and we thought that he should continue to take some of the medicine intravenously we give it to them to have their family doctor administer when they get home.

Q.—Do you give the instructions as to how to give the medicine? *A.*—It is given to the patient by the doctor that handled them in the hospital.

Q.—As to how the home doctor should use it? *A.*—A letter of instructions went along with it.

Q.—When was it you said you first tried the experiment with the hydrochloric acid in Milford, Kansas? *A.*—I don't remember the first time we tried it.

Q.—Just approximately? *A.*—I think it was in 1932; I think it was the year before I came down here.

Q.—Was that before Ferguson's article was written, that you are talking about? *A.*—I don't know when his article was written; I remember that I read Ferguson's article, and I had read other articles. It might have been at the beginning of 1933; but, anyway, I know I had used some of it and was using it in Kansas before we moved down here to Del Rio, Texas.

Q.—Have you read any further articles on the use of that substance in which the physicians stated that they found it was of no value? *A.*—I have read articles from physicians who said they had no results with it whatever.

Q.—You also know it has generally been disproven and disregarded by the medical profession? *A.*—No, sir, I don't think so, because I notice the manufacturers still make it and sell it, so, there must be a demand.

Q.—They make and sell it when you ask for it? *A.*—They sell it to others of the profession besides me; I am not the only one that buys it.

Q.—You don't know that as a fact, or that is your understanding—you know very well the medical profession has discarded the use of hydrochloric acid for the purpose you claim to get out of that? *A.*—I don't believe that.

Q.—You spoke about hydrochloric acid being one of the natural acids in the body, and you could say that about almost any acid, couldn't you, Doctor? *A.*—Not in the sense of what I meant when I made that statement; I was thinking of hydrochloric acid in the stomach.

Q.—Well, there are several other acids in the stomach, too? *A.*—Yes, sir.

Q.—What percentage of hydrochloric acid is in the stomach? *A.*—I will declare, I don't remember; 1.25, I believe, but I forget.

Q.—If there is some in there, some of the hydrochloric acid in the stomach, does that produce white blood cells in the stomach? *A.*—No, sir, I don't have any idea that it does.

Q.—Why not? *A.*—Because it is not coming in the stomach—I don't conceive of it coming in contact with the blood stream; it is put out in the stomach as an aid to digestion.

Q.—There is no way it would get in the blood stream, in your opinion? *A.*—No, sir, not as hydrochloric acid there in the stomach, no sir.

Q.—Now, Doctor, you talked about some experimental work or some study that you made in a colony of eunuchs, and where was that? *A.*—Indo-China, Ammon.

Q.—And your study of those eunuchs, that is, if they were castrated at an early age, they didn't develop a prostate gland? *A.*—Those I examined didn't have any evidence of a prostate.

Q.—What is it, in your opinion, from the examination that causes the growth of the prostate gland? *A.*—The prostate gland, in my opinion, is held in check up until the man attains a certain age, which I call the change of life in a man, by a balanced condition of his glandular system.

Q.—Wait, Doctor, you are not answering what I had in mind; maybe the question wasn't clear. What I mean is what is it that, between the time a baby is born and up until he becomes, well, until he reaches the age of puberty, what is it that causes the production and growth of the prostate gland? *A.*—I read in the literature that the prostate and the accessory sex glands are stimulated to grow by the male sex hormone, which controls them.

Q.—And the male sex hormone, where and how does it get up there? *A.*—The male sex hormone is made some place inside of a man's testicle, but it hasn't been definitely determined yet what part of the testicle that hormone is made in; that hormone, according to different investigators, stops at the age of puberty and remains normal along with the female hormone; the man has both hormones, the male and the female, until the break, we call it a break, on the anterior portion of the pituitary gland, and later on in life when a man grows old the cells in the testicles, whichever kind they may be, that makes the hormone, due to the infeeblement, don't make so much any more, and there is a less amount of the male sex hormone, and this takes the break off of the substance called prolan in the anterior part of the pituitary gland, and the basic cells in the pituitary where the prolan is supposed to be made exhaust themselves by the use of the prolan—

Q.—Well, I merely asked you what produced the growth of the prostate gland up to the growth of puberty—you say it is the sex hormones? *A.*—Yes, sir, the male sex hormone, that is my understanding.

Q.—The male sex hormone functions in that growth by passing through what canal in the body? *A.*—The blood stream.

Q.—And does that have anything to do with these ducts that you tie off? *A.*—In the sense of a hormone passing through the ducts, I don't think there is any relationship there at all.

Q.—Which secretion in the testes do you think passes, the external or the internal? *A.*—The external with spermatozoa.

Q.—Would that indicate to you that the external secretion didn't contain the sex hormone? *A.*—I don't think it does.

Q.—But you said you didn't know a minute ago? *A.*—I never said any such thing. I said I didn't know what part, and nobody else knows what part of the human testes makes those hormones.

Q.—It is definitely established what kind of tissue does? *A.*—Yes, sir; it is the interstitial tissue.

Q.—You can dissect and find what kind of tissue is in a particular part of it? *A.*—Yes, sir; but they haven't been able to put their finger on it and say which part is which that makes that hormone.

Q.—But if they just look and find where the interstitial tissue is they would know? *A.*—No, sir, because they have searched the interstitial tissue and they are not sure that it is made there; some are of the opinion that it is made in the inner tubules, and the epithelial and the interstitial, and one fellow has one idea where it is made and another fellow has another idea.

Q.—When you find a man late in life that you have the opinion that he has an enlarged prostate, as I understand Dr. Petermeyer's testimony, you tie off or ligate the ducts in order to cause a congestion, is that right? *A.*—In one sense I would correct that.

Q.—Let's have what other sense, if you don't agree with him? *A.*—My thought is, along with others, that tying off the ducts and blocking the passing of the semen so that it can't get out of the testes destroys the tubules, which we discussed previously, and destroys them and makes more room for the interstitial cells and germ cells to rejuvenate themselves and be more of them so that there will be more of the male sex hormone which can be made by the patient, and that is the way the benefits result; because many examinations have been made of these men before they had this done to them, and the amount of the sex hormones was found in the urine, and after the work was done the urine was examined later and found to be increased.

Q.—Where is the female sex hormone produced? *A.*—Somewhere in the testes of the male.

Q.—You think that by tying off the ducts you are going to get a disproportionate production, and you are going to change the balance? *A.*—It doesn't seem to change the balance; theorizing on it, you would theorize that way, to increase one you would think you would increase the other, but that has not been noted to occur.

Q.—That is not noted by you to occur? *A.*—I have talked with other men in this line of work and discussed it thoroughly, and I have seen many learned men; I have seen Dr. J. Elliott Smith, at the Saint Giles Hospital, London, England, and I went to see Professor Steinach at Vienna, but he was away on his vacation, so I talked with Professor Doppler, his assistant, and I went to Montreaux, Switzerland, and talked with Dr. Niehans, who has been doing this work, and Dr. Kocher of Berne, Switzerland, and I got their ideas as to whether it reconciled with me and whether I was on the right track, and I tried to go into those things.

Q.—Those men were doing that with the purpose or claim of sexual rejuvenation, were they? *A.*—Answering the question that way, I never asked what claims they were making, other than that we were discussing this work from a standpoint of enabling a man to empty his bladder.

Q.—They didn't claim it was an operation they were performing for the purpose of reducing the size of the prostate? *A.*—Yes, sir.

Q.—They didn't claim they were doing it for the purpose of treating prostatitis, did they? *A.*—Yes, sir; I believe I have some case reports from both of them on cases of prostatitis.

Q.—I thought you said you didn't discuss the purpose for which they were doing it, Doctor? *A.*—I said I didn't discuss the operation from a rejuvenation standpoint. You asked if they were claiming the operation was good for rejuvenation, and I said I didn't discuss it along that line.

Q.—When there is a change in what you call the balance between the male and female sex hormones in later life, I understand that you mean that the male hormone portion of it is decreased, is that correct? *A.*—That is what I am thinking, that the amount of male hormone is decreased and the female hormone seems to remain stationary.

Q.—Does that tend to make any physiological change in the man other than the prostate? *A.*—The testes soften about that time.

Q.—Do they tend to become effeminate? *A.*—No, sir; the man doesn't lose enough of his male sex hormones to take a change toward the feminine sex.

Q—Now, Doctor, in the ligature of these ducts it is quite true that nature tends to compensate in some manner for every blocked function, isn't that the general truth, in other words, any kind of an injury, why, nature has some compensating factors, like you are talking about the production of the white blood cells, and that is a relatively general rule, isn't it? *A*—I think more or less general, yes, sir

Q—Doctor, when you only tie off a few of those ducts between the testes and the epididymis, isn't it your opinion that nature compensates by making the rest of them do the work that all had done before? *A*—No, sir, I don't think so, I believe when you tie up a portion of those ducts that part of the tissue becomes congested and probably destroyed, and the tubules, no doubt, a portion of them become injured from that and they are replaced by something else

Q—You think nature causes a difference in the production of certain things or the certain parts that cause the male hormone, but you don't think it has anything to do with the parts that go through those tubes? *A*—In this instance nature wouldn't build a new set of tubules because a man is born with those, and if he loses a tubule he loses it forever and he is not going to grow another one

Q—If you tie off those, tie one of those off, and assuming there are nineteen others, why, tying off the one, why, the nineteen would do the work of the twenty? *A*—I wouldn't tie off just one

Q—I don't mean that, I just mean to say— *A*—I don't think so. A man would be plenty fertile yet, because a man, from that standpoint, is still passing plenty of spermatozoa

Q—And after that the nineteen would do the same as the twenty did before? *A*—I don't think nature would compensate to that extent.

Q—Are there any other portions of the body where you think nature wouldn't compensate? *A*—There might be, if you called my attention to them

Q—Those tubes aren't full all of the time? *A*—They are filled full of spermatozoa and semen, I believe, and I think they are filled all of the time, I don't think they are ever empty

Q—Constantly full? *A*—I think semen is coming out of those cells down there, and those globules, and gradually working up those tubules to where they are all of the time filled

Q—What kind of tissue are those tubules composed of? *A*—Tubular tissue

Q—Is tubular tissue elastic? *A*—No, sir, they are not elastic

Q—There is no way under the sun that those would stretch or enlarge to compensate for pressure, in your opinion? *A*—I doubt very much if they stretched any, they would, naturally, I suppose, when this secretion would be locked off, that is what causes—

Q—That is nature's compensation, isn't it? *A*—Not in the sense I am talking about, that is where nature can't help the tubules, and they are destroyed because they become overfilled and destroyed

Q—Well, then, it is your opinion that if you tie off all of those little ducts, efferent ducts, that as soon as or later you completely stop the external secretion from being produced in the testicles? *A*—I can't answer you that question, that could only be answered if I did the operation on a man and then later on took his testicles out and cut them open and looked to see what had happened.

Q—Now, Doctor, you talked about your dollar for pills business, and you have over the radio numerous times in the past told people to send a dollar or a dollar and a half to the Del Rio Drug Company and get prescription number 51 or number 65, or something like that, you have done that? *A*—No, sir, I never have since there was a Del Rio Drug Store, and I never have since I have been here mentioned any prescription by number, by any number whatever, as I told you, I promised the Federal Radio Commission in Washington in June 1930 I would never again describe those medicines by number over the radio, and prescribe them, and I never have called medicine by number over the radio since

Q—You did before that time? *A*—Yes, sir, I did before June 1930, I did

Q—All right, Doctor, you have taken symptoms of patients prior to that time and prescribed over the air, haven't you, from symptoms written in letters? *A*—It is like this those letters would come to me and they would say "I have been to my doctor—"

Q—Doctor, I guess you explained that before, why and how but it is a fact that you did it?

Mr Morriss Sr—He was answering the question, and he has a right to answer it, I think

THE COURT—Let him make the explanation afterward, but I think he should answer it

A—Yes, sir But I would like to explain

Q—Now, Doctor—

Mr Morriss Sr—Just a moment, the court said he has a right to explain it

THE COURT—If the simple answer of yes or no isn't enough, I will let him explain it.

A—I would like to explain this for instance, you wrote me a letter and said you were being treated by Dr so and so and that he told you that you had gallbladder or stomach disease or some other disease, and what was the matter, and that that was what you were taking the treatment for—"now, Dr Brinkley, my symptoms are so and so, and here is the way I feel, and what do you think about it," and that is the way most of those letters were answered on that basis, that these people were taking treatment from some doctor and they told me they were suffering from something

Q—Lots of those letters that you prescribed for over the air on that didn't state they had been taking a treatment from the doctor, a lot of them said "I have a back injury, and I have so and so," and you prescribed on the basis of what they told you in the letter? *A*—I probably have, I may have in some of those instances

Q—And lots of those instances where they wrote and said "I have gallbladder trouble" or "I have rickets" or something else, and you prescribed? *A*—Yes, sir When a patient says "I have so and so" I am of the opinion that the physician told them that is what he had

Q—You don't think that a patient gets it in his mind about what he has? *A*—Well sir, I agree with you on that, plenty of them get a notion in their head that is hard for a doctor to get out

Q—Do you think it is good practice to advise a man over the air that says "I have such and such" when you don't know which way he came to that conclusion? *A*—If you advise him something such as a simple laxative, or something like that, it is all right, but if you go to advising him on definite things and treatments other than that I think it is wrong

Q—All right, if somebody wrote and told you a child had rickets and you would prescribe thyroid extracts? *A*—Probably, in making a statement of that kind, I would have some background picture of this particular case

Q—Now, Doctor, as we consider that subject, isn't it a fact that a cathartic, for instance, might be very dangerous in a stomach case? *A*—A brisk cathartic on coming appendicitis, I think, is dangerous is a dangerous thing

Q—As a matter of fact when patients write in and describe a half a dozen symptoms it is quite possible those symptoms might be due to two or three different conditions, isn't it? *A*—Possibly

A—Doctor, you spoke with great reverence of your father as a doctor, but your father didn't advertise his wares, did he? *A*—Lord no, he was a poor, old country doctor

Q—Well, Doctor, I want to get one thing straight did you mean to state a while ago that the attorneys for the American Medical Association paid Crawford for giving that deposition by getting his release? *A*—No, sir, I didn't intend to convey any such meaning of that

Q—Let's have what you mean? *A*—This fellow Crawford came to me at my office in Milford, Kansas in 1932 while I was a candidate for governor, and he said for a consideration of $300 he would change this deposition that he had given to the American Medical Association while he was in the penitentiary in McAlester, Oklahoma, and he went on to relate to me the circumstances, said he was called into the warden's office—

Q—Did you say they promised to get him out? *A*—He said they promised to help him, and he told me—

Q—You didn't mean to convey the impression that there was any influence by the American Medical Association in getting that testimony? *A*—I am just telling you, and that is all I can do I can't do anything other than relate what Crawford said to me, and Crawford said they would do anything that they could

Q—Did Crawford tell you they did effect his release? *A*—I don't know that he said they did

Q—You didn't have that impression at that time? *A*—I was so disgusted with him, like any man would be under the circumstances

Q—Doctor, how many goat gland operations would you say that you and your associates performed since you introduced it? *A*—I suppose about six thousand, five or six thousand

Q—You say, now, those were experimental or do you say that it was the greatest remedy you ever found? *A*—I believe that the transplantation of glands is one of the greatest adjuncts to treatment for certain things we have, and I find that those glands are far superior even today than any product I can get like the male or female sex gland for the administration of a patient

Q—You have seen many of the patients in whom you have transplanted goat glands a considerable period after the transplantation haven't you? *A*—All down the years yes, sir

Q—You examined the testicle at that time? *A*—Nothing only by feeling of it

Q—For how long would you say, after you put that gland in there were you still able to feel it? *A*—You seem to be of the opinion that all of my gland operations were in the testicle, and I think I started to relate the other day that I transplanted them in different ways and I related one of them in the testicles

Q—Well, speak of the one in the testicles? *A*—We better say there are very few of those done, very few of them performed, the majority of those gland implantations were made in the fasciae of the scrotum or in the cremaster or the cremasteric muscles of the scrotum

Q—You could feel them? *A*—Yes, sir

Q—How long a period of time could you feel them? *A*—I have observed them—well, in one particular case—and of course, I am not mentioning that case to say that all cases were like this because they weren't but you asked me how long, and I will say I remember one case that I could feel nodules and lumps in there for a period of two years afterward

Q—What would be the average would you say? *A*—The average of those would be—the majority of them would practically find nothing left after a period of six months, a few of them, quite a few of them I found to be able to feel of them nine months afterward

Q—What did you feel when you felt them? *A*—Feel a round nodule like a little marble, or something like that

Q—Hard scar tissue? *A*—No, sir

Q—What did it feel like? *A*—I thought so, but I cut some out to see, and some of them had glandular tissue in them

Q—As a matter of fact, no male sex hormones are produced in goat glands? *A*—There are, no doubt, female and male sex hormones when they come out of the goat, it is evidently full of them

Q—Do you believe that the sperm is specific with the species? *A*—I am not speaking about sperm, I am speaking about hormones

Q—Then, your goat glands had nothing to do with anything but hormone production, is that what we are to understand? *A*—My idea of whatever good they did to put in a man caused him to urinate, and so forth, and he was getting that sex hormone to balance his own up to the level with the female sex hormone, and that is where the good came about

Q—Was it the overamount of female hormones that caused the enlarged prostate? *A*—It seems to be, 'cause we go and inject the female sex hormone into the pig or the rat, and by continual injections of that in the pig and in the rat they have cancer of the prostate or enlarged prostates, and by that we produce cancerous prostates and enlarged prostates, and, on the other hand, if you take both of the male and the female hormones of equal proportion and inject them at the same time there is no observation or change one way or the other

Q—Here is what I am trying to get at if the male sex hormone, if that is what causes the growth or accounts for the growth of the prostate gland, how was that consistent with your theory that in later life, adding more male hormones reduces the size of the prostate gland? *A*—When the male hormone becomes reduced in size it releases other substances held there called prolan, and when this is put in the blood stream then the prostate—the production of the prolan is stopped and the prostate ceases to enlarge

Q—Then, it is the prolan that caused the enlargement? *A*—The prolan is set loose by the action of the sex hormone

Q—The prolan is what causes the enlargement? *A*—In connection with the sex hormone

Q—The sex hormone is something that sets it loose, and it doesn't have anything else to do except that the prolan is on the prostate is that your thought? *A*.—No, sir, my thought isn't that way

Q.—I just want to get what it is, Doctor. What I want to know is the difference between the size in the prostate gland being because of the hormone, and, yet, in old age when you cause the production of more male hormone you say that minimizes or reduces the size? *A.*—A man has a normal amount of male sex hormones running from 10 to 24 units, and that is what has been estimated as being the normal amount of male sex hormones, and as long as man maintains that the release of prolan is not observed, but when that amount is decreased the release of prolan is observed and enlargement of the prostate takes place, so if we don't have the proper amount of sex hormones in the man's testicles to hold the prolan in the pituitary gland in balance and not let it go to overproducing itself we are going to get our enlarged prostate, and we have to have that checked, and the sex gland, the male sex gland is the one that checks against the prolan in the pituitary.

Q.—You know that in the development from child into man there are often cases of a delayed development? *A.*—Yes, sir.

Q.—Would you say in connection with that that when a person doesn't assume his full sexual maturity you must also find an enlarged prostate? *A.*—When these testicles haven't descended in children and haven't developed we find the prostate hasn't developed, and that is what gives me the idea that the male sex hormone has to do with the growth and development of the prostate gland because the undescended testicle, if both are undescended, it shows that the boy grows up just like a eunuch and has no prostate.

Q.—Now, Doctor, are goat glands used in the manufacture of commercial hormone preparations? *A.*—I don't know.

Q.—As a matter of fact, they get the greatest supply of that from entirely different substances? *A.*—I don't know where the supply comes from, since they have been able to identify the hormone.

Q.—They get it from the urine of pregnant mares? *A.*—That is one source.

Q.—You never heard of them using goat glands for that purpose? *A.*—I never heard of using sheep glands or any other kind, because it would be too expensive, it would be impossible to use, I think, for the extract of that hormone.

Q.—Now, Doctor, in this new technic you now have you say you have widely discussed that with people, and you let everybody know about it, and you have written articles to the medical journals asking them to print? *A.*—New technic?

Q.—Yes, sir? *A.*—I haven't written a thing to the medical journals, because I was turned down before and I knew I would be turned now.

Q.—As a matter of fact, you stated in your biography here that you would never reveal your technic of any kind to anybody again, didn't you? *A.*—I declare, I don't know what is in the biography.

Q.—You did have a little trouble with a couple of fellows who worked for you taking your goat gland and going elsewhere and performing that operation? *A.*—Owensby and Dragoo at Milford have their own hospital there, and they have been there ever since I left Milford.

Q.—And you didn't have any resentment of that at all? *A.*—I thought they treated me unfairly when both of them had been on my staff and employed by me, and to break loose from me.

Q.—Didn't you send out circulars and letters and advertisements in newspapers denouncing them for having done that?

Mr. Morriss Sr.:—I believe that is pretty far afield.

THE COURT:—I think it is legitimate cross examination.

Q.—How about that, Doctor? *A.*—I am sure I never put anything in the newspapers.

Q.—You did send out some circulars? *A.*—Probably did send out letters to my patients, very likely did.

Q.—In other words, you resented the other doctors having, in your opinion, stolen your treatment, is that right? *A.*—I just felt like they didn't treat me fair.

Q.—By using your treatment, is that it? *A.*—No, sir, by quitting my employ, abruptly breaking off from me without doing so in a legitimate business-like way.

Q.—You wanted to keep that process yourself, didn't you, Doctor? *A.*—I didn't want those fellows working for me to get up and set up a hospital and go in competition with me.

Q.—In your biography isn't this statement contained, referring to that episode and referring to the doctors by letter, Dr. A and Dr. B, and then it said "this forced Brinkley to do his own surgical work in Kansas; a court order permitted this, but this court order was of doubtful permit, and at any time Brinkley might find himself without authority to operate his own hospital or perform his own surgery. He came to some definite conclusions that the discovery and all improvements in his technic had been made by him alone, and he had been betrayed by A and B, and never again would he give a doctor a chance to do this to him, and he would let no other doctor in on his secrets"? *A.*—The betrayal didn't refer to them setting themselves up in business, but from business methods and things they did in my office that certainly brought me to the conclusion and opinion that I never would have any doctors working for me again and take them into my confidence like I did those two fellows.

Q.—You haven't broadcast your new treatments to the world, then, have you? *A.*—Well, I am broadcasting every day.

Q.—I said your new treatments or methods to the medical profession? *A.*—As I told you, I haven't written any medical journal articles since the previous time when I offered them and they weren't accepted; I don't consider it would be any use for me now to get out a letter to the doctors or try to get something in the medical journal.

Q.—You know that Ferguson wrote about the hydrochloric acid solution, don't you, and the doctors tried it? *A.*—Yes, sir, I know Ferguson wrote about it.

Q.—Also, that it was generally discarded?

THE COURT:—You asked that before.

Q.—Now, Doctor, there has been some talk here about your inviting other doctors to see your goat gland operation; as a matter of fact, that happened when your license was under fire, and you then said to the Kansas Board to appoint some doctors to watch you, isn't that it? *A.*—That is one time, but that is just merely one instance among many.

Q.—And those doctors did come and watch your operation? *A.*—Some of them did. I don't think all did.

Q.—Dr. Nesselrode was one? *A.*—Yes, sir.

Q.—And, then, they made full reports to the Kansas Board? *A.*—Very likely did; it is my understanding that they did.

Q.—And the license was, thereafter, revoked?

THE COURT:—That has been in evidence here a half dozen times that the license was revoked. We will recess now, gentlemen, until two o'clock.

At this time a recess was taken until 2 p. m. of said date; which time having arrived, the following proceedings were had, to wit:

Questions by Mr. Reynolds (resumed):

Q.—Dr. Brinkley, just a few more questions. Do I understand it that you formerly called what you now call your surgical technic the compound prostatic operation? *A.*—Not exactly, no, sir. When I was using the word the compound that was back in the days when I was doing work on the vas deferens, implanting the glandular tissue and things like that, and that was what I was speaking of as the compound operation.

Q.—Was that the same as the four phase operation? *A.*—When I was speaking of that I was putting in the glands, cutting out a section of the vas and injecting medicine through the vas and bringing down some muscle tissue and implanting it into the testicle.

Q.—I understand that, but is there a difference there between your four phase operation and then what you next called your compound operation? *A.*—Yes, sir.

Q.—There is a difference? *A.*—Yes, sir, there is a difference.

Q.—Is there a difference between the compound operation and what you refer to as the compound prostatic operation? *A.*—I don't think I ever used the word compound prostatic operation, I don't think I used that.

Q.—You haven't used any other name for this present surgical technic? *A.*—When I first started using it I thought about calling it a budding operation just for the purpose of using a term.

Q.—Doctor, you spoke this morning about thyroid gland transplantations. I believe you say you witnessed that over in Europe some place. That was discarded, wasn't it, after some experimentation? *A.*—I don't know, sir.

Q.—You haven't heard of it being followed up in this country and being generally used, have you? *A.*—I don't know.

Q.—Now, Doctor, there is another thing I want to get clear here. In your opinion was your four phase or any operation employing the goat gland effective in curing sterility caused by gonorrhea? *A.*—No, not a gland transplantation, it would certainly have no effect on sterility caused by gonorrhea.

Q.—And you don't have that claim regarding your compound operation, do you? *A.*—No, sir.

Q.—Now, about sterility caused by mumps? *A.*—Back when I first began using these glands I put the glands into some patients that had the mumps and after the glands were transplanted into them their wives conceived and bore children and that gave me a thought that possibly the absorption of that glandular tissue was stimulating the man's testicle into the formation of sperm cells. Possibly my misconception in my eagerness and enthusiasm was overdrawn.

Q.—Do you cure sterility caused by mumps by your present technic? *A.*—Oh, no.

Q.—You don't make any such claim? *A.*—No.

Q.—Doctor, this is a touchy subject, but quite truthfully, in your own estimation, are you the greatest prostatic specialist in the world? *A.*—You know, I certainly don't think so. I imagine there are many men who are probably greater than I am.

Q.—But you like to have people write on these contests stating that you are? *A.*—The announcer over the radio station fixes up those announcements and puts them out.

Q.—What are you going to do with those letters? Have you formed plans on those? *A.*—I will send each one of those people a book.

Q.—You are going to judge the best one and give them the prize, though? *A.*—Well, that is a statement made over the radio. I imagine I will call in several people at Little Rock. I imagine we will have thousands of them. I doubt if I will be able to read them all.

Q.—What book is this you are going to send them? *A.*—A little book, probably a little book entitled "After Twenty-One Years."

Q.—What is the general nature of the book? *A.*—Talks about the radio station and the silver wedding anniversary of Mr. and Mrs. Brinkley, reproduction of x-ray pictures we have made of former patients and my boyhood.

Q.—Talks about your former patients? *A.*—Yes.

Q.—And benefits you have done for them? *A.*—Yes, sir.

Q.—Doctor, may I ask what is the value of that enormous ring on your left hand there? *A.*—I paid $4,300 for that ring, sir.

Q.—Do you think that is the value of it? *A.*—I don't know what it is worth. That is at least what I paid for it.

Q.—How about the one on your right hand? *A.*—This?

Q.—Yes, sir? *A.*—That ring is worth about a $1,000.

Q.—How about your stickpin? *A.*—Fifteen hundred dollars.

Q.—Your tieclasp? *A.*—Oh, about $800.

Q.—How many automobiles is it you have now, Doctor? *A.*—I will have to go to counting up.

Mr. Morriss Sr.:—I don't know that that has anything to do with the question of this libel suit, but if he wants to pursue it I just don't know why. If the gentleman thinks he can get some prejudice in that way I don't want to make any particular objection.

THE COURT:—Well, if you don't want to object you ought not to rise to your feet. If you want to object the court will rule on it.

Mr. Morriss Sr.:—I just think that that inquiry has gone far enough, that is what I think about it.

THE COURT:—Overrule the objection.

Mr. Morriss Sr.:—Note the exception.

Q.—How many automobiles, Doctor? *A.*—Well, now, you will pardon me until I figure up a little bit, will you? Over on the farm in North Carolina I have a couple over there and down at the citrus groves I have a couple down there. That is four. At the hospitals we have three or four. Well, say that is eight. I am not sure. And I think we have four here at home, something like that. I guess about a dozen.

Q.—These here at home are all large cars, aren't they? *A.*—No, we don't have—if you are thinking of limousines, we don't have any limousines here, we have nothing larger than a five passenger car here.

Q.—What about this red car you ride around in, what kind of car is that? *A.*—That is a Cadillac 16 coupé.

Q.—How many times is your name on there, Doctor? *A.*—I never counted it, I don't know.

Q.—About thirteen or fourteen times, isn't it? *A.*—I don't know, I never counted it.

Q.—In naming your automobiles you forgot your bus in Little Rock, didn't you? You have a bus running between your two hospitals? *A.*—No, that is an old Cadillac.

Q —Doctor, you originally built this radio station over in Villa Acuna, didn't you? A —XER? I built that, the first one, myself

Q —How many towers were sticking up, the antenna? A —We put up two and then the third one

Q —That third one was put up after the station was temporarily closed, or was it? A —No, that third tower was up there when the station did close

Q —Sometime between its opening, then And then you didn't put it up in the first place? A —The two towers were put up and then within a year I think the third tower was put up

Q —Now, that third tower is located just about the center of the other two except it is a little to the south toward Mexico, isn't it? A —Right

Q —What is that third tower for? A —To give a directional effect to the station

Q —In other words, your broadcasts don't go South, but they go North? A —Yes, they go South the amount of power that goes South is the exact power that is in the antenna I will just give you an illustration as it is today Today there is 500,000 watts put in the antenna Now, South they get the effect of a 500 000 watt broadcasting station, but directly up this way they get the effect of a million watts broadcasting station

Q —Now, Doctor, just as a general estimation what is the value of the real estate owned by you? A —In North Carolina I would estimate the real estate over there is worth $75,000 The citrus groves down here in the Valley $50,000

Mr Morriss Sr —By the way, I believe we object to all that as having nothing to do in this case, being irrelevant and immaterial and incompetent to establish any issue and we move the exclusion of—the withdrawal of the questions and the answers so far and make the objection to anything further along that line

Mr Reynolds —Your honor, there are several decisions in various states I don t think we have found one in Texas, I will say that, but in many states that the financial condition of the plaintiff in a libel action may be introduced into evidence Now, it is generally known that the financial condition of the defendant can be but there is a division of authority on the financial condition of the defendant—of the plaintiff I am urging those decisions in that way upon the Court as being a reasonable one You will find that all definitely set out, I think it is page 251 of Newell on slander and libel

THE COURT —It seems to me if there is inquiry as to the source of his revenues, where it might have come from, it might have some relevancy I think the question of his income was gone into rather thoroughly the other day He testified what his income was for three or four years I don't think I will let any further questions along that line go in

Q —It is a fact, is it, Doctor, that you have had continual financial success in the practice of your medicine, though, ever since you started advertising? A —No, I haven't had continuous success, I have had some years that were quite unsuccessful

RE-DIRECT EXAMINATION

By Mr Morriss Sr

Q —Doctor, since the lengthy discussion about the theories of the prostate that we have had do you or not still hold to the opinion that your operation benefits patients and mankind? A —Absolutely

Q —Do you or not know whether the prostatic operation by ligating the epididymis has been accepted and approved and is now practiced by a good many other doctors other than yourself? A —Yes, that technic is used by other physicians

Q —Counsel asked you the other day and there was testimony, the testimony of Mr Tingle, about a proceeding filed at Dallas at one time in which it was tried to revoke your license in Texas What became of that proceeding? A —Dismissed

Q —Doctor I did want to ask you one other matter, and that was with reference to the effect, if any, of this article at the time it came out upon your own feelings? A —It made me feel ashamed and made me feel embarrassed and hurt my feelings generally It made my wife feel ashamed and my daughters—

Mr Reynolds —Just a minute The rest of the family aren't claiming damages here I think that should be stricken from the answer

THE COURT —The feeling of his wife or the balance of his family might have had some effect on him I will let the jury consider it

Mr Morriss Sr —I think that is all

RE-CROSS EXAMINATION

By Mr Reynolds

Q —You said this technic is being used now by other physicians How many can you tell us that use the ligation of the efferent ducts? A —Steinach, Elliott Smith, St Giles Hospital in London and Dr Neihans is using it, and I think there are quite a few physicians in the United States using it

Q —Do you know that there are any in the United States using it? A —I believe there are

Q —You don t know? A —I don't care to swear to it That is an opinion

Q —Now, regarding these Texas proceedings in regard to your license, they were dismissed, there never were any hearings on that, were there? A —No

RE-DIRECT EXAMINATION

By Mr Morriss Sr

Q —Doctor, with reference to your best information, how about doctors in San Antonio and other cities and towns, have they gone to using it?

Mr Reynolds —I object to the Doctor's best information

Witness excused

TESTIMONY OF J H DAVIS

J H Davis testified on direct examination by Mr Morriss Sr that he is a doctor, living in Little Rock and licensed in Arkansas, Texas, Mississippi, Louisiana and Oklahoma He came to Del Rio in 1933 and moved with the Brinkley Hospital to Arkansas His testimony then proceeded as follows

Q —What do you do, Doctor, what is your connection there? A —Well I am examining physician, and of course I recheck some people, not many not as many in Little Rock as I did here

Q —Have you witnessed and assisted in any of these prostate operations that Dr Brinkley performs? A —I have been in the operating room a few times when Dr Brinkley was operating and, in fact, when the other surgeons was operating, too

Q —And have you had occasion to inquire—let's see you have been there something over five years, have you? A —Something like that.

Q —Have you had occasion to acquire an intimate knowledge of the operation and of the treatment, examinations and all that that are given to the patients in that hospital? A —I do about the examination and I have had observation of the operation I have never done the operation

Q —We are not going to take the time, Doctor, to ask you with reference to the details of the examination that patients are put through That has been testified to But I just wanted to get from you the matter of—of this prostate operation and the question of its success or not? A —Well, my observation has been that it is very successful

Q —Now, about how many—you spoke about the opportunity to recheck What do you mean by that? A —Well, that is patients that have been operated on and later, six or eight months, possibly a year or a number of years later returned for a recheck, a general check up

Q —Is that for examination of their physical condition generally? A —Yes, sir

Q —In those instances do you examine them or have you done so? A —I have made the recheck examination, a good many of them

Q —What did you find with reference—in rechecking, I mean, what do you generally find, that is any exceptions or otherwise, what do you find with reference to the condition when they come back? A —Improvement in some instances and in some instances satisfactory cures

Q —Doctor, you are not talking loud enough You said improvement in some instances and in some instances satisfactory cures? A —Yes, sir

Q —What about the prostate, the condition of the prostate after those operations, whether or not it has been changed in its size, reduced or otherwise Tell us about that? A —Well, the prostate, it is owing to the condition of the prostate when it was received, about the time that there would be any change or not, and some of the prostates that are only enlarged from an infiltration will reduce quicker than one that is fibrous

Q —What do you mean one that is fibrous? A —Well, it is a little bit hard

Q —Well, I am talking about those that come back six or eight months or a year and so forth, what do you find their condition to be then? A —I find improvement

Q —On a question of reduction or not, that is what I am trying to get at, the reduction of the size of the prostate? A —Well, they are reduced The prostates are graded from one plus to minus and three plus and three minus and so on You take a three plus prostate, one that is infiltrated from infection will reduce after the operation to normal size over the course of seven or eight days That has been my observation Those that are larger and have an infiltration of glandular tissue and have become a little bit fibrous, they don't reduce so much, but those that are two plus might be a two minus in eight months or twelve months on recheck

Q —What do you mean by that just explain about the size? A —A two plus prostate in the first stages of enlargement from its normal size that is a two plus prostate, and a two minus would be a little bit—or three minus or three plus would still be larger

Q —In other words, if I understand you, you grade them according to size? A —According to size, yes, sir

Q —Up to what maximum size do you find them? A —I have found a few that I graded them out as four plus

Q —What size would that be? A —Well, that would be something the size of the ordinary grapefruit, pretty large

Q —I want you to tell the jury whether or not, Doctor, from your observation and experience with these operations on the many patients you have seen whether or not the operation is in your opinion considered a success or otherwise? A —Well, it is a success

Q —Is it or not beneficial to the sufferer? A —Yes, sir

Q —Does it or not—I am not talking about every case—but does it or not relieve the patient from his sufferings, and if so the percentage of cases? A —I wouldn't know the exact percentage, but the per cent relieved is very large They may be relieved of urinary trouble The prostate may not go down so rapid, but they will be relieved of urinary troubles and pains adjacent thereto, a large percentage

Q —Now what about the continuation of that improvement, does it extend is it permanent in its nature or is it temporary or how? A —Well, it seems to be permanent from my observation of the number of rechecks that I have had in the last five years

Q —Have you or not then had occasion to recheck those whose operations are as much as four or five years old? A —Yes, sir, I have rechecked them further back than that, ones operated on at Milford Kansas I wasn't associated with Dr Brinkley at Kansas, but there have been patients to the hospital that I have rechecked here in Del Rio that was operated up there back in 1930 and '31 and '32 and possibly, then back before that, but I don't remember their names

Q —What did you find in those older cases, that is, what I mean is the condition? A —Well, we had the record before us, the size of the prostate when they entered, and the most of them were normal would be my recollection about it so far as the size of it was concerned

Q —I suggest you tell us what part you have in the physical examinations so as to manifest what you know about the condition when they come there? A —Well, the patient registers and then they are sent to my office for a physical examination and I make the physical examination and grade the prostate and return it back to the laboratories

Q —Then you do have opportunity to know what their condition is when they get there as to their prostatic trouble, do you? A —Yes sir

Q —Doctor, would you tell us—by the way, how long have you been practicing medicine, did I ask you that? A —Well, no I graduated from medical college in April 1912, I think it was No, April 4, 1904

Q —Well, have you been practicing ever since? A —I have been in the active practice ever since

Q —How did you happen to go with and when did you go with Dr Brinkley in his hospital? A —Well, I think it was 1902—

Q —You mean 1932? A —1932, I mean I carried a patient from my home town to the hospital at Milford, Kansas

Q —From your home town where, Doctor? A —Waldo, Arkansas

Q.—Go ahead. A.—I carried this patient up there and he was examined and accepted and was operated on, and I stayed there in the hospital with him for the period of seven days. And he drove my car back from Kansas in the seven days. That is, the most of the time. We took time about and he drove some as we went up, I carried him up in my car and brought him back in my car, and I rechecked him then in 1933 or 1934, I dis-remember, here at Del Rio and he was well and all right. And then when Brinkley came from Kansas and established his hospital in Del Rio I had a license in Del Rio and I believed in his work after staying in his hospital up there for a week.

Q.—Now, then, go ahead? A.—I wrote him and asked him if he had a place on his staff, that if he did I would consider it, and he wrote me he did.

Q.—Did you have any other patients that went to him or you took to him? A.—I carried another one to him in the spring of 1933 from Stamps, Arkansas, and he was rejected, they said he was too far advanced and they wouldn't take him. They were the only patients I ever carried to the Brinkley Hospital.

Q.—That was before you made your connection with the hospital? A.—Yes, sir, that was before I ever made any connection with him.

Q.—You had met Dr. Brinkley, then, on the occasion of your visits? A.—I met Dr. Brinkley at Little Rock in the spring some time of 1932. He was down there and made an address to the medical association. Myself and wife drove up there. I wanted to see what he looked like. I never had seen him.

Q.—Was that before or after that that you took the patient up to Milford? A.—I carried that patient up there before that. He was in Canada. My patient was brought back home before the medical association met. So I drove up to Little Rock to hear him. That was the first time I ever heard him.

CROSS EXAMINATION

By Mr. Reynolds:

Q.—What medical association was that you say, Doctor? A.—The Eclectic Medical Association.

Q.—Are you an eclectic doctor yourself? A.—No, sir.

Q.—You have never attended any meetings where Dr. Brinkley addressed them, a county medical society? A.—No.

Q.—You didn't mean to infer that? A.—No, it was the State Eclectic Medical Association of Arkansas. I am a member of the allopathic tribe.

Q.—Doctor, now in your examining of patients you said something about grading the prostate and then sending it to the laboratory. What do you mean by that? A.—Well, after the physical examination is made and the condition of the prostate is described on the examination blank as to its size and as to its tensity and so forth, then they are sent to the laboratory for x-ray work.

Q.—The patient is? A.—Yes, sir.

Q.—Not just a section of the prostate? A.—Oh, no.

Q.—Now, Doctor, how many times is it you have seen Dr. Brinkley himself operate? A.—A good many times. I wouldn't say how many, but a number of times.

Q.—Have they all been cases of prostatic enlargement? A.—Yes, sir.

Q.—No prostatitis? A.—Well, an enlarged prostate might have some inflammation and it might not have.

Q.—Any for prostates containing cancer? A.—How is that?

Q.—Any for prostate glands containing a cancer? A.—I have never seen him operate on one that was supposed to have cancer.

Q.—He does that though, doesn't he? A.—Not that I know of. If he does I don't know it.

Q.—Now, this patient, this first patient that you brought to Dr. Brinkley, did he perform the goat gland transplantation in that patient? A.—No, sir, Dr. Brinkley didn't do that; Dr. LeGrew did it.

Q.—It was a goat gland operation? A.—Yes, sir.

Q.—And how about the second one that was brought? A.—The second one I brought he was rejected, there was no operation made on him. He was too far advanced.

Q.—Did they give him treatments? A.—No, sir.

Q.—They send him home? A.—I brought him back home.

Q.—Is that patient still living? A.—I think he is.

Q.—And that was seven years ago? A.—It was in the spring of 1933. He went to Shreveport and had something done. I don't know what he had done.

Q.—Now, these present operations, that is, what Dr. Brinkley calls his surgical technic, you understand that term? A.—I have seen him do it, yes, sir.

Q.—How many times have you seen him do that? A.—Oh, quite a number of times.

Q.—And have you rechecked patients on whom he has done that? A.—A number of them.

Q.—What is the average length of the incision that you find, the scar, to be when you recheck? A.—Something like about from a half to three-quarters of an inch, and some would possibly be an inch long if there is a hydrocele in connection with it the incision is longer.

Q.—But if it is not it is only half or three-quarters of an inch long? A.—Ordinarily where there is no hydrocele.

Q.—With an incision of that size it is your understanding Dr. Brinkley lifts the testicle out? A.—He don't lift the testicle out unless there is a hydrocele. He may lift a portion out.

Q.—What portion? A.—The head of the epididymis.

Q.—What does he do then, inject something into it? A.—He has a needle threaded and he picks up the head of the epididymis and puts the needle around in there and brings it around there and ties it.

Q.—Around what, the head of the epididymis? A.—Through the head of the epididymis.

Q.—Now, I don't understand just exactly how that works. Will you explain the position of the epididymis on the testicle so we will get that clear? A.—It is attached to the testicle.

Q.—By what? A.—By the vas deferens along the side of the testicle. The vas deferens enters at the head.

Q.—It isn't attached by the vas deferens? A.—I say the vas deferens enters in the head of the epididymis and the epididymis is attached by the tissue in some way, I don't know.

Q.—Well, then, it is a position like this, like this finger over my fist? A.—Yes.

Q.—And the operation you have seen him perform, he just runs through the head of the epididymis with a piece of linen thread and then ties that, does he? A.—Yes, I think so. He has a string and he ties it anyway.

Q.—And you have examined that operation closely? A.—How is that?

Q.—Have you watched him closely do that? A.—Just standing in the operating room looking on, trying to see what I could see.

Q.—In what position is that string after it is tied? Is it vertical or horizontal? A.—It is horizontal, it is tied horizontal in a surgeon's knot, I presume.

Q.—Then has he done anything else in there? A.—That is all, he drops it back and sews it up.

Q.—Is that all the operation consists of? A.—Sometimes he injects the epididymis before he goes through the head of the epididymis.

Q.—Injects it with what? A.—Well, mercurochrome, I guess.

Q.—You have never seen him do that, have you? A.—Yes.

Q.—And that goes right in the epididymis? A.—No, it goes in the vas.

Q.—Well, you mean he injects it in the vas rather than in the head of the epididymis, is that right? A.—Injects it in the vas and it goes up it, I guess, because the urine is red after the injection.

Q.—Have you ever seen him cut out a section of the vas? A.—Well, I have seen him do that, too.

Q.—Have you seen him tie off a section, ligate a section of the vas? A.—They ligate the end next to the testicle. The other end is left open.

Q.—When they ligate the end next to the epididymis there do they also ligate the head of the epididymis in another manner? A.—No, that is two different operations.

Q.—Now, Doctor, you are the one that receives and examines the patients in the first instance, are you not? A.—Yes, sir.

Q.—You make the diagnosis? A.—Yes, sir, the tentative diagnosis.

Q.—Then who makes the final diagnosis? A.—Well, here in Del Rio Dr. Brinkley, when he was here, made the final diagnosis. When he was away I think Dr. Petermeyer made the diagnosis, and up at Little Rock Dr. Osburn does it.

Q.—Dr. Osburn is doing most of the surgery up there now, isn't he? A.—Yes, sir.

Q.—Dr. Brinkley operates how many times a week? A.—I haven't seen him operate but one week since I have been up there. That was this last April a year ago he operated on some forty-five or forty-eight patients that week.

Q.—Just before he left Del Rio was Dr. Brinkley doing very much surgery then? A.—He was doing some, not very much. Petermeyer was doing the most of it. That was last year.

Q.—How long did it take him to perform this operation when you witnessed it? A.—Well, about from twelve to fifteen minutes.

Q.—They charge $750 for that operation, is that correct? A.—That is what I have been told.

Q.—And now, Doctor, these follow-up patients, that is when you recheck them, do you go out to their homes and do that? A.—No, they come to the hospital.

Q.—And from all over the country? A.—Yes, sir.

Q.—At their own expense? A.—Yes, sir.

Q.—Is there no further charge on that? Do you charge them for that? A.—No further charge on that, everything is free when they get to the hospital.

Q.—Well, when you discharge a patient from the hospital there you are quite sure that he is cured or relieved before you discharge him, aren't you? A.—As a rule. In some instances they might not be relieved altogether, but they want to go home and we let them go and give them full instructions as to diet and prescriptions.

Q.—Then it is this latter class that generally comes back for a recheck, isn't it? A.—Well, I don't know, I don't remember.

Q.—Well, you have the record before you when you make the recheck? A.—No, sir.

Q.—You don't know which class is the largest? A.—Well, I don't know which class would be the larger, as far as that is concerned. The majority of them come back for rechecks, though.

Q.—Have any of them that you have ever seen operated on come back for a recheck, to your knowledge? A.—Yes, I remember a few. There are so many of those patients you couldn't recall the names, but there is a complete record made of every patient. I remember a few.

Q.—What per cent of the patients come back for a recheck? A.—I couldn't tell you.

Q.—Haven't you an estimate? A.—Well, I am inclined to think around 60 per cent come back anyway, maybe more than that. I don't know how many come back.

Q.—It wouldn't be as low as 5 per cent, would it? A.—No, sir.

Q.—How many would you say come back during the period of a year, the last year? A.—Well, I couldn't say, but we have them there all the time.

Q.—It would be in the thousands, would it? A.—No, I don't think it would run into that, not thousands. Possibly it would run up to a thousand that would come back in a year. I haven't kept account of those things and I don't know.

Q.—Now, Doctor, which hospital is it you are stationed at now in Little Rock, the town hospital? A.—The city hospital, Twentieth and Schiller Avenue.

Q.—You have seen records on patients up there where all that was done to them was the removing of residuary urine, haven't you? A.—Not unless it was a rejection. There are many of our patients carrying residual urine when they come.

Q.—As a matter of fact, relieving them of that will make them feel better? A.—Undoubtedly it will, yes.

Q.—They will look better? A.—Yes, sir.

Q.—Give them a week's rest and that does them a lot of good and makes them more energetic? A.—Undoubtedly.

Q.—After you relieve them of the residuary urine, taking the average case that comes to you as a prostate enlargement, it is quite some time before they will have any complaint again, isn't it? A.—I can't say just as to that, whether they are carrying a lot of residual urine. I have patients come to me carrying as much as fifty-four residual, and it would be impossible to draw it all off at once because if you did you would have to put sterile water back because—

Q.—Do you do any of that drawing off? A.—I have done some at Del Rio, but not any at Little Rock.

Q.—You work for Dr. Brinkley on a salary, do you not? A.—Yes, sir. If you draw it all off when you have so much residual urine you would then have diverticula, drawing too much off.

Q.—Have you observed Dr. Petermeyer operate? A.—Yes, sir.

Q.—And the technic he uses is the same as that of Dr. Brinkley? A.—The same thing.

SATURDAY, MAY 27, 1939

THE ST. LOUIS SESSION

The St. Louis session of 1939 takes its place along with all the other recent annual sessions of the American Medical Association as setting a peak for medical assemblages. Foremost again among the features of the meetings was the Scientific Exhibit, pronounced by most of the physicians in attendance the greatest opportunity for concentrated graduate education available anywhere in the world. In each of the exhibit spaces scientists recognized for their accomplishments in various fields of investigation, teaching and practice demonstrated the highlights of their work. In many places visitors found it difficult to pass through the aisles because of the great numbers of physicians assembled to hear lectures and to see demonstrations. Simultaneously motion pictures were being used to reveal the actual application of new technics in medical care. Special exhibits devoted to the diagnosis and treatment of pneumonia, of diabetes and of fractures were especially useful because they were cooperative features which thoroughly digested the subjects with which they were concerned.

The attendance at the annual session was 7,412, which made this, of course, the largest meeting of physicians ever held in the city of St. Louis, a figure which compared favorably with the numbers attracted by meetings held even in the centers of population. The hotels of the community were taxed to their capacity, as were all the other convention facilities. Yet the quality of material available was so excellent that few physicians complained when minor difficulties were experienced. Indeed, exhibitors in the technical exhibit expressed universal gratification in the attendance and in the interest shown. On the last day of the session all were well-nigh exhausted by the manner in which their capacity had been taxed by the interested questioners. The technical exhibits again indicated that manufacturers realize the value of scientific demonstration rather than salesmanship in interesting the prospective purchaser in the medical field.

In the Scientific Assembly, new technics of education had been developed under the leadership of Dr. James Paullin, chairman of the Council on Scientific Assembly. Combined meetings, particularly on the last day of the session, and the panel discussions which prevailed in the general scientific sessions, attracted large numbers of physicians, whose interest was shown by the fact that questions were asked of the participants in the panels for more than an hour after the preliminary discussions were made. The features of the scientific program were, of course, the newer investigations in industrial medicine, the use of sulfanilamide and sulfapyridine, the vitamins and the glands. This material will be reflected in the pages of THE JOURNAL within the next few months.

The sessions of the House of Delegates were notable for unanimity of action and for the harmony which prevailed. The topic of greatest significance was the point of view in relationship to the proposed Wagner health act. As will be seen from the minutes of the House of Delegates, the reference committee to which this matter was assigned prepared a concentrated analytical report which was adopted by the House of Delegates on the first motion without a dissenting vote and even without any attempt at discussion by individual members. Interesting also to the House of Delegates was the action taken regarding the amendment to the By-Laws in order to increase the capacity and function of the Council on Medical Education and Hospitals. By the new action the Council will be increased to nine members, who are to be selected because of their special interest in the various aspects of medical education, including premedical education, undergraduate and graduate education, as well as the work of the hospitals. A preamble to this resolution indicated that it was the desire of the House of Delegates to keep the work abreast of the newer developments in this field, particularly the certifying boards in the medical specialties, the associated residencies in hospitals, and the work of the special societies which have grown apace in medicine in recent years. Attention was attracted also by the resolution regarding membership of Negro physicians in the American Medical Association and requesting a special representative of women in the House of Delegates. Both the resolutions and the subsequent action seem to have been somewhat misunderstood by the press. Eventually it was made clear that Negroes may hold membership in county medical societies in many of the states, and that even in southern portions of the United States attempts are constantly made to provide Negro physicians with the full scientific benefits of medical organization. Moreover, it was again emphasized that under the democratic system of government the county medical societies must be the determiners of their memberships. Part of the difficulty arises because government relief agencies in the South refuse to utilize the services of Negro physicians for Negro patients, claiming lack of

membership in the American Medical Association as the reason. The resolution asking that a woman be regularly seated in the House of Delegates was defeated. Women have on occasion been regularly elected to the House of Delegates and have served efficiently. There is at present no bar to the election of women by any constituent association.

During the week the press, the radio and all other avenues of publicity were cooperative so that there were numerous broadcasts, both locally and nationally, and the pages of the local press were replete with material developed by the convention. Most of the great press services were also represented and papers at a considerable distance used much material from the St. Louis meeting. The accuracy of the scientific reporting was most commendable.

Entertainment at the St. Louis session was profuse. Every available space in every hotel was constantly in use for special events, many of them arranged by fraternities, alumni associations, honorary societies or specialistic groups and many of them developed by the Woman's Auxiliary in the course of its annual session. Indeed, the officers of the Woman's Auxiliary expressed themselves as more than pleased with the annual session and with the arrangements that had been made. The House of Delegates was entertained on the opening night by a puppet show in which leaders in scientific and other medical affairs were caricatured in relationship to current activities. Particularly impressive was the opening address of Aesculapius, beautifully delivered with organ accompaniment:

Attention Sires—for I would have you gaze
Upon yourselves—as mystic mummers haze
Your mortal imperfections!

Out of the realm of shadows I have come
And with me brought my merry puppet crew.
They've acted—for the Pharaohs—at their Court,
With wise men of old Persia did consort,
And now they hold their mirror up to you.
You are my own, and we have welded strong
Eternal bonds that make us act as one.
Together we have battled, heart and soul,
'Gainst error with perfection as our goal
While pledging love of ease and self to shun.

The curtain rises now upon the proof
Of stupid man's unwillingness to see
What our self sacrifice has brought
As battles for his life and health we've fought
In shielding him from mortal's end's decree.

The farewell speech of Aesculapius reflected the inspiration of the meeting:

I leave you now, but not for long I trust,
Affection's made of heart throbs—not of dust.

The way of flesh is weak, but be ye strong
My precepts follow and ye'll ne'er do wrong.

Continue sons the poor and weak to aid
In gold of grateful hearts, you will be paid.

Your ear, your eye, your brain, your heart, your hand
You lend to others when you join my band.

Your ear must list to every cripple's plea
Your eye must hurt of soul or body see.

With kindly hand, the tear of sorrow dry
Though weary, haste to answer suffering's cry.

Your brain and heart must find the easy road
For straggling feet that stumble 'neath their load.

Be fearless when you level straight your lance;
With life and health at stake, ne'er trust to chance.

Before we go my puppets bid me say
We love you all and with you fain would stay.

If we have made you laugh, with joy we're filled.
To bring smiles to you is all we willed.

Adieu! We've had a happy time
With hearts entwined, we'll all sing Auld Lang Syne.

DR. JAMES B. HERRICK RECEIVES DISTINGUISHED SERVICE AWARD

The second award of the Distinguished Service Medal and citation by the American Medical Association was tendered during the annual session at St. Louis to Dr. James Bryan Herrick of Chicago. The first award last year was made to Dr. Rudolph Matas of New Orleans. By the system of selection this award has already come to be recognized as one of the most important within the gift of the Association. After nominations are made through the Distinguished Service Award Committee, five names are sent by them to the Board of Trustees. The Trustees select three of the five, and the House of Delegates, at its first session, selects one of the three. This year the three names nominated to the House of Delegates were those of Dr. James Bryan Herrick, Dr. Chevalier Jackson of Philadelphia, and Dr. Edward Jackson of Denver. The report of the House of Delegates published in this issue indicates the vote cast.

Dr. James Bryan Herrick was born Aug. 11, 1861, in Oak Park, Ill. He attended Oak Park High School and the Rock River Seminary at Mount Morris, Ill. He then received his A.B. degree from the University of Michigan in 1882. For a time he taught in the Central High School at Peoria, Ill., where he acquired a love of good literature and a facility for expressing himself in the English language. Through an association with Moses Coit Tyler he developed a great interest in Chaucer. Dr. Herrick then took up the study of medicine, receiving the degree of Doctor of Medicine from Rush Medical College in 1888. His internship was served in the Cook County Hospital and in 1889, after completing his internship, he married Miss Zellah P. Davies of Oak Park.

Dr. Herrick has contributed greatly to the periodical literature of medical science, he has taught in his Alma Mater and he is widely known for his contributions particularly to our knowledge of coronary thrombosis. Indeed, it has been said that his articles on coronary thrombosis have done more to force clinical recognition of the condition and to stimulate clinical and experi-

mental study than all other writings on the subject. Probably most significant was the contribution on "Clinical Features of Sudden Obstruction of the Coronary Arteries," published in 1912. In his career as a physician he also has been instructor in medicine at Rush Medical College from 1890 to 1894, adjunct professor from 1894 to 1900, professor from 1900 to 1927, and he is now emeritus. He has been attending physician at the Presbyterian Hospital in Chicago since 1895 and a member of the board of trustees of the Lewis Institute since 1903. He has also been president of the Association of American Physicians, of the Institute of Medicine in Chicago, and of the American Association of the History of Medicine. In 1930 he received the Kober Medal of the Association of American Physicians for Research and Scientific Medicine. In 1931 he gave the sixth Harvey Society Lecture at the New York Academy of Medicine on the Coronary Artery in Health and Disease, and in 1933 he was elected honorary fellow of the New York Academy of Medicine. In 1932 he received the honorary degree of Doctor of Laws from the University of Michigan, and in January 1939, at the 194th convocation of the University of Chicago, the honorary Doctorate of Science was conferred upon him.

Throughout his career he has been of vast assistance to young men and a builder of medical institutions. He was founder and first president of the Chicago Society of Internal Medicine. From 1928 to 1934 he was a member of the Judicial Council of the American Medical Association. By this second award the House of Delegates still further enhances the significance of its Distinguished Service Medal.

ENZYME THERAPY OF GRAM-POSITIVE INFECTIONS

The isolation of a soil bacillus capable of destroying gram-positive micro-organisms in the animal body seems to offer an encouraging lead toward a new therapeutic procedure. About ten years ago Dubos [1] of the Rockefeller Institute began a systematic search for environmental saprophytes. His initial attempt sought some nonpathogenic fungi or bacteria which could use the type-specific capsular polysaccharide of the pneumococcus. Finally from certain peat soils a saprophytic bacillus was isolated which was apparently able to decapsulate type III pneumococci in vitro. Enzymes isolated from this bacillus, however, were inactive against other types of pneumococcus and did not have any effect on nonpneumococcic polysaccharides. Dubos found that this saprophytic enzyme would protect mice against type III pneumococcus infections but was without general pneumococcidal action. Moreover, even though the enzyme did decapsulate type III pneumococci it did not demonstrably injure the living portion of the bacterial cell.

Dubos [2] therefore attempted a new technic, recently described. Soil samples were repeatedly moistened with aqueous suspensions of gram-positive cocci. After many months of selective adaptation an unidentified spore-bearing bacillus was isolated from one soil sample which was capable of producing lysis of living gram-positive micro-organisms. This soil bacillus is gram specific, attacking equally well staphylococci, streptococci, pneumococci and all other types of gram-positive micro-organisms thus far tested. The soil bacillus, however, is wholly inert against the gonococcus and other gram-negative bacteria.

From subcultures of this lytic bacillus, it is reported, the active principle can be set free by autolysis and can be isolated in a state of relative purity by acid precipitation at refrigerator temperature. The active principle thus isolated is heat labile and is nondialysable through a collodion membrane. One mg. of the dried extract is capable of producing lysis of 1,000,000,000 living pneumococci within one hour. Staphylococci and streptococci are also acted on but somewhat less rapidly. Lytic action is most rapid at 37 C., all action ceasing at 0 C. As little as 0.0001 mg. of the dried extract added to 5 cc. of nutrient broth will prevent the multiplication of a massive inoculum of pneumococci (e. g. 10,000,000 micro-organisms). Bacteriostasis of staphylococci and streptococci requires somewhat larger amounts of the extract. Streptococci incubated in the presence of even minute traces of extract, however, lose their ability to reduce methylene blue in the presence of dextrose. Morphologic alterations are not demonstrable in these physiologically deficient streptococci.

When tested for its possible therapeutic value the Dubos lysin has been found effective in preventing and curing gram-positive infections in laboratory animals. A single intraperitoneal injection of 2 mg. of the extract, for example, will protect a white mouse against as many as 100,000 minimum lethal doses of type I, II, III, V or VIII pneumococcus (other types not yet tested). Protection against even larger doses of pneumococci may be effected by repeated injections of the saprophytic extract. Moreover, the extract exerts a curative effect when administered several hours after experimental infection with virulent pneumococci. Similar therapeutic effects have been demonstrated after experimental infections with hemolytic streptococci.

The possible therapeutic value of the Dubos enzymes in human medicine has not yet been tested. If this new lytic agent should prove to be of positive clinical value, the Dubos technic of selective cultivation of environmental flora will stimulate further experimentation. Perhaps soil bacteria effective against tubercle bacilli or other pathogenic groups may yet be found.

Current Comment

NATHAN B. VAN ETTEN—PRESIDENT-ELECT

The general practitioner as a leader in medical affairs was recognized by the House of Delegates of the American Medical Association in the St. Louis session when it elected Nathan Bristol Van Etten to be President for the years 1940-1941. Dr. Van Etten received his degree in medicine from Bellevue Hospital Medical College in 1890 and he has practiced in New York City since that date. In 1906 he became visiting physician to the Union Hospital and has been constantly associated with that hospital. He has also been medical director of the Morrisania City Hospital since 1929 and president of its staff since 1932. Throughout his career he has given unstintingly of himself to every medical and public effort to which he was called. His quality of leadership is shown by the fact that he has been president of the Bronx County Medical Society, of the Bronx Borough Medical Society, of the New York Society of Medical Jurisprudence, of the Medical Alumni of New York University, of the Greater New York Medical Association, and also president and trustee of the Medical Society of the State of New York. This long list of presidencies reaches its culmination in election to the presidency of the American Medical Association. In the Association he served as a member of the House of Delegates in 1920 and 1923, continuously from 1926 through 1935, and also in the special session of 1935 which considered the Social Security Act. He was elected vice speaker of the House of Delegates in 1933 and served in that position until he was elected speaker in 1935. While in the House of Delegates he was a member and frequently chairman of many important reference committees. While speaker in 1936, 1937 and 1938 he earned the respect and admiration of the delegates by his calm manner, his absolute justice, his leadership and his unwavering fidelity to the principles of the American Medical Association. In his address of acceptance, Dr. Van Etten again dedicated himself to the work of the Association and made a plea for united action, saying:

NATHAN B. VAN ETTEN, M.D.
PRESIDENT-ELECT OF THE AMERICAN MEDICAL ASSOCIATION

> Yesterday you adopted a report defining your position in relation to the proposed Wagner health act. It will have small value, however, unless the whole medical profession of the United States is educated to fully understand it.
>
> Every delegate must realize his official obligations as never before and carry home to every single practitioner in his state a full consciousness of the importance of this declaration of principles. That practitioner is potentially one of the most powerful persons in the democracy. If he can be made to see his duty to his country and educate his patients to a realization of the dangers of centralized control of medical practice, your action of yesterday will be sustained.
>
> In the name of welfare, gentlemen of the House, the practice of medicine as you know it and as you hoped it would become is to be destroyed. The functions of the most highly educated group of professionals in the world are to be taken over by bureaus operated by adventurous amateurs.
>
> The time has come for the concerted action of every doctor in the United States.

LETHAL METHEMOGLOBINEMIA

Bradley and his colleagues [1] of the University of Wyoming have shown that bovine asphyxial death following the ingestion of certain toxic hays is due to the formation of methemoglobin in the blood stream. In one region of Wyoming in 1934 twenty-nine head of cattle died within a few hours after eating well cured oat hay. The Wyoming investigators, therefore, studied hay intoxication experimentally. They found that 11 pounds (5 Kg.) of one local sample of oat hay would kill a 350 pound (160 Kg.) steer in about nine hours, that a water extract of the same hay caused another steer to show asphyxial symptoms from which he later recovered. In both cases a chocolate brown color was observed in the blood, which was shown chemically and spectroscopically to be due to methemoglobin. The erythrocytes are not laked, and the plasma remains clear and straw colored. Another calf fed a smaller amount of toxic hay did not develop symptoms or methemoglobin at the end of six hours. By the ninth hour, however, the animal presented typical symptoms and had a high concentration of methemoglobin in the blood stream. By the end of twenty-four hours, both symptoms and methemoglobin had disappeared. Toxic oat straw develops in certain restricted areas in Wyoming and Colorado. Whether this is due to soil conditions, to some unrecognized toxic weed or to a fungous or virus infection of the oats has not yet been determined. The fact that the oat toxin is water soluble and heat stable, however, will be of great value in its ultimate isolation and identification.

ORGANIZATION SECTION

PROCEEDINGS OF THE ST. LOUIS SESSION

MINUTES OF THE NINETIETH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ST. LOUIS, MAY 15-19, 1939

HOUSE OF DELEGATES

First Meeting—Monday Morning, May 15

The House of Delegates convened in the Ball Room of the Hotel Statler and was called to order at 10 a. m. by the Speaker, Dr. H. H. Shoulders.

Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman, Dr. Deering G. Smith, New Hampshire, who reported that 153 delegates with proper credentials had registered and that that number was one of the largest registrations in advance of the meeting.

Roll Call

The roll call was dispensed with, on motion of Dr. E. G. Wood, Tennessee, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried.

The Speaker announced that the report of the Reference Committee on Credentials would constitute the roll call of the House for the transaction of business.

Adoption of Minutes of San Francisco Session and of the Special Session

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. John Q. Myers, North Carolina, and carried, the House dispensed with the reading of the minutes.

It was moved by Dr. John Q. Myers, North Carolina, seconded by Dr. A. T. McCormack, Kentucky, and carried, that the minutes of the San Francisco Session be adopted as printed.

Dr. Charles E. Mongan, Massachusetts, moved the adoption of the minutes of the Special Session held in Chicago in September 1938. The motion was seconded by Dr. J. R. Westaby, South Dakota, and carried.

Distinguished Service Award

Dr. Arthur W. Booth, Chairman of the Board of Trustees, presented the following report:

The Committee on Distinguished Service Award of the American Medical Association submitted five names to the Board of Trustees. The Board, in accordance with chapter VI, section 5, of the By-Laws, has selected by ballot the following names for presentation to the House in alphabetical order: Dr. James B. Herrick, Chicago; Dr. Chevalier Jackson, Philadelphia; Dr. Edward Jackson, Denver.

The Speaker appointed as tellers Drs. Harvey F. Garrison, New Jersey; William A. Ellingwood, Maine, and Charles B. Reed, Illinois.

The tellers spread the ballot and the Secretary announced that 154 votes were cast, of which Dr. James B. Herrick received 63; Dr. Chevalier Jackson 69 and Dr. Edward Jackson 22.

Since no nominee received a majority of the votes, the Speaker announced that another vote would have to be taken and that, in accordance with the rules, the name of the nominee receiving the smallest number of votes, namely, Dr. Edward Jackson, would be dropped from the ballot.

Dr. Deering G. Smith, Chairman, Reference Committee on Credentials, stated that 165 delegates had registered, and the Secretary announced that Dr. James B. Herrick received 81 and Dr. Chevalier Jackson 79 votes. The Chairman declared Dr. James B. Herrick, who received a majority of the votes cast, to be elected by the House to receive the Distinguished Service Award of the American Medical Association.

Address of the Speaker, Dr. H. H. Shoulders

The Vice Speaker, Dr. R. W. Fouts, Omaha, presided while the Speaker, Dr. H. H. Shoulders, read his address, which was referred to the Reference Committee on Reports of Officers:

To the Members of the House of Delegates of the American Medical Association:

Mr. Speaker, Members of the House, Guests:

By your suffrage, I have the honor of greeting you this morning as your presiding officer.

Since last we met I have taken occasion to review, in a way, the proceedings of this House for a period of years. It was undertaken as a dull task but proved to be an interesting experience. The effect was, among others, to enhance my admiration for the genius and loyalty of this House of Delegates.

It must be remembered that this body is composed of 174 delegates, representing the medical profession in every state in this Union, including Alaska, Hawaii, the Panama Canal Zone, the Philippine Islands and Puerto Rico. You are so widely scattered that there is little opportunity for contact with one another in the interim between sessions. A wide variety of local conditions obtain in the areas represented. Every possible shade of opinion and every possible local interest, both personal and professional, are represented. You are democratic in concept, composition and conduct.

The House is in session for a few hours each day for not more than three days as a rule. A relatively small amount of time is available for deliberation and debate. No ready reference library is at hand. Almost every session of the House has been called on to consider and act on issues of vital importance not only to the medical profession but to the people of this country as a whole.

Notwithstanding all these conditions, one finds in the Proceedings of the House a golden thread of consistency which runs straight through all the actions taken on all issues presented which in any way touch the fundamental principles to which you have given allegiance. It would be natural, under the circumstances, for errors to occur and for actions taken in one session to be in conflict with those taken in another session one or many years before. Yet this has not occurred.

It is of interest and may be of value to consider why this is so. Such a striking result might easily be explained if your actions were controlled by a dictator or a boss. Fortunately, this House is not subservient to any such person, and more fortunate still is the fact that no one seeks such power, nor could one obtain it under our democratic organization.

It seems to me that not one but several factors are responsible for this result. Of first importance is our code of ethical principles. Not alone because it is in existence, but because the spirit of it is so deeply rooted in our professional life, it has given to us, as a profession, a philosophy. Our loyalty to these principles is not based on self interest; their appeal is to the noblest instincts of mankind and the highest concepts of human relationship and conduct. Our convictions with regard to them give us courage to declare ourselves in relation to them when occasion arises. Some years ago I heard a philosophy expressed to the effect that a man is fortunate who finds himself anchored

to ideals. The reason given for such a philosophy was that the existence of a man is transitory but that ideals live on through the ages.

Another factor, possibly of greater importance than either of the other two, is our faith. We have faith in the merits of democratic processes as a means for the accomplishment of the highest and best in human welfare. By such processes our philosophy has been evolved. They have not stood in the way of progress. To the contrary, they have augmented sound progress, as our history shows. We know that these processes appear to be slow at times. We know also that attempts to accomplish desirable ends in a hurry by brushing these ideals aside may have the effect of destroying the most important element in human welfare; viz., freedom itself.

We know that, if we doctors had the power to dictate to patients instead of advising them, a still greater increase in longevity might result. But we know also that such an achievement, at the price of freedom, would be the worst bargain that could possibly be made. We have never sought such power for ourselves. We naturally oppose it in others.

We do believe in coordinated effort on a democratic basis. We believe in the closest coordination of effort as between the legislative, executive and judicial branches of the American Medical Association on the basis of mutual respect and confidence—all working to a common purpose. We have faith in one another. There is all about us obvious evidence of lack of faith. There is lack of faith of one group of citizens in another group. There is lack of faith in government and in the various agencies of government. There is lack of faith of one government in another government. Some citizens have expressed by word and act a lack of faith in the merits of democratic processes. Furthermore, influences have been at work and divers means have been employed to destroy faith in these processes.

Nothwithstanding all these conditions and influences, the record shows that we have stood by our faith. We have held on to our ideals. In my opinion, we have thus earned a liberal measure of public confidence. I know of no other group of men who have stood by convictions or even observed pledges with greater fidelity. I entertain the belief that the time will come again, maybe soon, when a grateful public will applaud our loyalty to ideals and principles, as was done not so long ago.

May I suggest that we approach the duties of this session with such a faith in one another, in the several departments of our organization and in the future.

In Memoriam

It becomes the melancholy duty of the Speaker to call the roll of those who have in times past responded to the roll call of this House but who in the last year have responded to the last roll call on earth.

A. W. Baugh, Pennsylvania, 1913.
Carl Boettiger, New York, 1935 Special Session; 1936.
Nelson O. Brooks, New York, 1917-1918; 1926.
John W. Burns, Texas, 1922-1932; 1934; 1935 Special Session; 1935-1938; 1938 Special Session; Member of Judicial Council, 1937—.
Richard C. Cabot, Massachusetts, 1907; 1915.
John Champlin, Rhode Island, 1902-1904; 1906-1909; 1912.
A. J. Crowell, North Carolina, 1909; 1915; 1922; 1925-1926; 1929-1931.
George Edmund de Schweinitz, Pennsylvania, President-Elect, 1921-1922; President, 1922-1923.
T. A. Felch, Michigan, 1903; 1909.
Frederick H. Flaherty, New York, 1927-1932; 1935-1938.
J. C. Flippin, Virginia, 1934; 1935; Special Session; 1935-1938; 1938 Special Session; Member, Council on Scientific Assembly, 1936—.
P. Maxwell Foshay, Ohio, 1902-1903.
L. M. Gates, Pennsylvania, 1913; 1915.
J. Norman Henry, Pennsylvania, 1926-1931; 1933.
Vard H. Hulen, Texas, 1911.
J. Allen Jackson, Pennsylvania, 1932-1934; 1935 Special Session; 1935-1937.
Charles H. Goodrich, New York, 1932-1934; 1935 Special Session; 1936-1938.
Alexander Lambert, New York, 1911; Third Vice President, 1909; President-Elect, 1918-1919; President, 1919-1920; Member of Judicial Council, 1911-1918 (chairman of that council, 1912-1918).
S. L. Ledbetter, Alabama, 1910.
Hugh F. Lorimer, Ohio, 1908.
Philip Marvel, New Jersey, 1902; 1923; 1928-1930; 1934; 1935 Special Session; Third Vice President, 1900-1901; Trustee, 1904-1920; Vice President, 1925-1926.
Ephraim R. Mulford, New Jersey, 1929-1934; 1935 Special Session; 1935-1937; 1938 Special Session.
J. H. Murray, Pennsylvania, 1924; 1927.
Frank P. Norbury, Illinois, 1904.
Hugh T. Patrick, Illinois, 1912, 1919-1920.
William G Ricker, Vermont, 1925-1928; 1930; 1932-1934.
William H. Seemann, Louisiana, 1915-1916; 1919-1926; 1930-1934; 1935 Special Session; 1935-1938; 1938 Special Session.
Walter H. Snyder, Ohio, 1905.
H. W. Van Allen, Massachusetts, 1912-1913.
Frederick L. Van Sickle, Pennsylvania, 1916-1917; 1923.
Victor G. Vecki, California, 1913-1916; 1919; 1922-1929.
H. D. Wood, Arkansas, 1927.

The lives of these men constitute a part of our living record of achievement.

It is fitting that the House pause at this moment to take some appropriate action in remembrance of them.

At the request of the Vice Speaker the members of the House arose and stood for one minute in silent tribute to the memory of departed delegates.

An amended motion of Dr. A. T. McCormack, Kentucky, that when the House adjourns it adjourn in memory of all the former members of the House of Delegates who have passed on was seconded and carried.

Reference Committees

The Speaker announced the personnel of the Reference Committees:

SECTIONS AND SECTION WORK

George Gray Ward, Chairman.....Section on Obstetrics and Gynecology
Thomas B. Throckmorton.....Section on Nervous and Mental Diseases
Curtice Rosser.....Section on Gastro-Enterology and Proctology

William Weston.....Section on Pediatrics
E. S. Hamilton.....Illinois

Address of President Irvin Abell

The Speaker resumed the Chair and presented the President, Dr. Irvin Abell, Louisville, Ky., who delivered the following address, which was later referred to the Reference Committee on Reports of Officers, with the exception of that portion referring to the Wagner National Health Bill, which was referred to a Reference Committee on Consideration of the Wagner National Health Bill that was subsequently appointed:

Mr. Speaker and Members of the House of Delegates:

The past year has seen peak development in many of the activities of the American Medical Association. An all time high has been reached both in membership in the Association and in subscriptions to THE JOURNAL. The various councils and bureaus have been continuously active in promoting their scientific and educational objectives. Liaison meetings between the Council on Foods, the Council on Pharmacy and Chemistry and representatives of the federal bureaus have developed assistance in the administration of the Food, Drug and Cosmetic Act. The newly created Council on Industrial Health sponsored a conference held in Chicago in January attended by representatives of the various agencies interested in industrial health and laid the ground work for improvement in this special field.

The Council on Medical Education and Hospitals has devoted much thought and effort to the problem of graduate education and training with the object in view of establishing standards and increasing facilities for the acquisition of training on a basis of the requirements established by the specialty boards. This problem is an intricate one but gives promise of solution with the cooperation of the agencies interested in it. Events of momentous importance involving medicine have evolved from the changing social thought of recent years. The recommendations of the Technical Committee on Medical Care, a subcommittee of the Interdepartmental Committee to Coordinate the Health and Welfare Activities of the federal government, presented to the National Health Conference, held in Washington last July, envisaged a comprehensive program for the participation of the federal government in health activities. At the special session of the House of Delegates held last September these recommendations were carefully considered and the attitude of the American Medical Association toward them was clearly defined in the report of the reference committee unanimously adopted by the House.

The committee appointed by the Speaker of the House in compliance with its instructions has held two all day conferences with the Interdepartmental Committee, the first one October 31 in response to the resolution of the House of Delegates which directed it to confer with such agency or agencies as might be designated by the President of the United States, the second one January 15 on the invitation of Miss Josephine Roche, extended through Mr. G. St. J. Perrott, secretary of the Interdepartmental Committee. Since the Interdepartmental Committee did not, at either meeting, submit a draft of the proposed legislative enactment for the translation of its recommendations into activity, the discussions were of necessity limited to principles. Your committee closely adhered to the principles and policies adopted by the House of Delegates both at its special session and at its previously held regular session. Discrepancies between the data and statistics assembled by the Technical Committee on Medical Care and those assembled by the American Medical Association were emphasized where such might ultimately influence the application of the Technical Committee's recommendations. Expansion of public health, maternal and child welfare services with limitation of curative measures to private practice where available; utilization of vacant beds in present hospitals on a per diem basis; the construction of new beds and diagnostic health centers on a basis of economic, geographic and health needs with standards for hospital administration and for professional personnel; perpetuation of hospitals and health centers; the formulation of plans for the care of the medical needy determined by local and financial needs under medical and local state supervision; the approval of sickness compensation and of voluntary insurance for hospital and medical service, and unqualified opposition to the suggestion in recommendation IV that the individual states initiate studies and plans for the care of all their people on a tax paid basis are briefly the points for which your committee contended. Compulsory sickness insurance is a more appealing and a more euphonious title than the one which accurately identifies it, namely sickness tax. Mr. Falk of the Technical Committee tentatively set the level at which compulsory plans would operate at an income of $3,000 or less. Federal statistics reveal that but 7 per cent of the population enjoy an income above this amount, if and when a compulsory plan becomes operative in all the states at this level, 93 per cent of the population will be covered thereby.

Our interview with the President was held at the suggestion of and was arranged for by the Surgeon General of the Public Health Service. President Roosevelt was most gracious and affable and discussed both his interest in an increase in hospital facilities and a wide distribution of medical care on a basis of need and as well the budgetary difficulties which the program entails. At his suggestion the chairman of your committee briefly but clearly outlined the position of the American Medical Association to each of the five recommendations made by the Technical Committee.

On January 23 the President presented to the Congress his message on the National Health Program with a recommendation for its careful consideration and study. On February 28 Senator Wagner of New York introduced into the Senate of the United States a bill, S. 1620, entitled "A Bill to provide for the general welfare by enabling the several states to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance and training of personnel." Although the bill is actually an amendment to the Social Security Act, the bill proposes that, if it is enacted, it be called the "National Health Act of 1939." Assuming that this bill has the endorsement of the federal agencies responsible for the National Health Program, it has afforded opportunity to study the means by which it proposes to put into effect the recommendations of the Interdepartmental Committee and by comparison to see how far it harmonizes with the approval in principle given by the House of Delegates at its special session. The American Medical Association at no time expressed its opinion on the amounts of money to be expended in such a program, but it is of interest to note that the Wagner bill proposes an expenditure of $98,250,000 for the fiscal year of 1940, $123,500,000 for the fiscal year of 1941 and $334,000,000 for the fiscal year of 1942, with no limit on the amounts during 1941 and 1942 for public health work, for grants for mental and tuberculous hospitals, for grants for medical care, for grants for temporary disability compensation and for administration, and, further, that for the fiscal years subsequent to 1942 there is no specified limit on expenditures for the accomplishment of any of the purposes of the act.

While no specific mention is made of compulsory sickness insurance, the measure introduces the principle of allotment of federal money to the individual states for medical care, by the Social Security Board, without specifying the means to be used in the individual states for providing such service other than to demand the approval of the Social Security Board, being silent as to the permissible extensions and improvements of medical care that a state may make and as to whether such care shall be provided through a state medical service or by a system of state health insurance or by payment for services on a fee basis. The administrative agencies mentioned in the bill are the Children's Bureau, the United States Public Health Service and the Social Security Board, final and complete authority for carrying out the purposes of the act resting in these three departments. Granting the occurrence in a rural or isolated community of disease which from their classification would come under each and all three of these agencies, satisfactory and competent administration would seem extremely difficult, if not impossible. Such a contingency but enhances the contention of the American Medical Association for a Minister of Health, a unified agency for the correlation of all health activities. The bill does not provide for means of determining the local need for the various services it proposes to furnish, a matter of importance repeatedly

emphasized by the House of Delegates, and no stipulation as to the utilization and improvement of existing hospitals is mentioned. These are but a few of the points that demand your consideration and study in aiding in the development of a health program for the nation to which we are by experience, knowledge and conviction committed, its fundamental objectives being an expansion of public health, maternal and child welfare services, approved care to the indigent and the medically indigent, and an extension of hospital and diagnostic facilities.

Another movement which intimately concerns medicine is to be found in the activities of the Department of Justice in securing an indictment of the American Medical Association for monopolistic practices operating in restraint of trade. During the past summer an assistant to the Attorney General gave releases to the press in Washington accusing the American Medical Association of illegal practices and threatening it with criminal prosecution, thereby promoting an antagonistic mental attitude on the part of the public toward the Association. In a release of August 1 the following appears: "In the event that voluntary cooperation results in constructive proposals going beyond the elimination of illegal practices, the Department would adhere to its previously announced policy of submitting such proposals to the court as a basis for a consent decree." In other words, in order to escape trial the American Medical Association must admit guilt and agree to do more than the law requires. On December 1 another assistant to the Attorney General, in addressing a public audience in Milwaukee, outlined the "charges which the Department of Justice is presenting to the Grand Jury," "what the Department's lawyers" had learned, "the background of the controversy," "that the American Medical Association has adopted an official policy of opposition," and so on. This particular attorney at the time was engaged in conducting the inquiry by the grand jury and later signed the indictment brought by it. From time immemorial grand jury investigations have been presumed to be secret, in order to prevent antagonistic mental attitudes on the part of prospective jurymen who will sit on the trial jury when and if an indictment is obtained. One can but wonder if the actions of these two attorneys are in harmony with the ideals and traditions of the American Bar Association.

The fundamental point at issue in the indictment of the American Medical Association is as to where the power of policing professional organizations shall lie. Heretofore by common consent this power has been vested in the organizations themselves, which have established standards of qualification, training, attainment, character and conduct for those desiring to enter their ranks and for the members desiring to remain in their ranks. This power has been exercised in good faith and with good intent for the protection of the public. Should a conviction be obtained and upheld by the appellate courts, the policing power would be transferred to the federal government, which would then determine qualifications for membership, articles of expulsion, and the like. While this legislation was primarily aimed at the American Medical Association, it is apparent that many other organizations, professional and business, have an interest in it, since that which applies to one will apply to all. The House of Delegates, at the San Francisco session, declared in no uncertain terms its intention to see the then threatened indictment through to its ultimate conclusion; the principle involved is one on which there can be no compromise. As your President, it has been my duty and my privilege to visit many of the component bodies of the American Medical Association and it is with definite gratification and pleasure that I bear witness to their loyalty to the principles for which the Association stands and of their earnest and sincere desire to cooperate in bridging the gap between the accumulation of medical knowledge and its equable, wide distribution in the shape of good medical service.

In conclusion permit me to express to the members of this House and through them to the membership of their respective bodies my profound gratitude and thanks for their constructive criticism, their loyal support and their faithful cooperation in maintaining the ethical institution of medicine, the record of which today stands unparalleled in all the world in the prevention, control and cure of disease.

Address of President-Elect Rock Sleyster

The Speaker presented the President-Elect, Dr. Rock Sleyster, Wauwatosa, Wis., who delivered the following address, which was later referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

The interest and attention of this body, when in annual session the past few years, has been largely occupied with threats to the science of medicine by social and governmental agencies, ambitious to revolutionize orderly procedure in the continued development and distribution of medical care. Such agencies have promoted an impression that there has been a "breakdown" in medicine as there has been in agriculture, industry, railroads, building and manufacturing. We know that this is not true. We know that medicine, in fact, is about the only major endeavor which has not failed but on the contrary has improved its quality of service as well as its distribution during the depression years. Such needs as exist are only those coexistent with the needs of the necessities of life; they have been met by American medicine as no other needs have been satisfied.

I have wondered, during the past few sessions of the House of Delegates, if possibly, with attention focused on these threats, we have not paid too little attention to the purposes for which the American Medical Association was organized and to the established activities in which it is engaged. I dimly recall one of the old "Dooley" stories of how the hoodlums of the third ward stood in front of Mrs. Murphy's house calling her names, she so busy talking back to them from the front door that she did not see or hear two of their delegation raiding her icebox via the kitchen entrance. And so this morning I want, from this point, to ignore the noise out in the street and briefly to redirect your attention to some of our activities and to some threats to them from an entirely different quarter.

Previous reports to the House of Delegates have called to your attention growing concern over the ever increasing number of medical organizations. While we have made a gain of approximately 14,000 members in the past five years, a number equal to the entire memberships of the Michigan, Ohio, Indiana and West Virginia state societies, and a contradiction to any claims of strife and disintegration in our ranks, the fact remains that many organizations, some perhaps unnecessary, are a drain on the time and interest of our members. After all, the American Medical Association always has assumed and always must assume the responsibility of medical progress and the defense of all that has been accomplished in the past. No other group is representative of all branches of medicine, no other group has the organization necessary, and no other group includes in its membership practically all members of all independent groups.

Most of these independent societies were originally organized for purely scientific purposes in some particular field. I believe most of their members agree that matters of broad public policy should, and must, be the responsibility of the American Medical Association. Yet occasionally an officer of one of these societies, in interview or speech, expresses endorsement of policies in conflict with those established by this House, representative of the whole profession. No one would deny such officer the American right to express his individual opinion —but is he authorized to speak in the name of his society? An officer of the American Medical Association may not voice unapproved policies, and it must be remembered that in the public eye an officer cannot be dissociated from his organization. In these days of danger to medicine, each scientific organization, if in agreement that primary responsibility rests with the American Medical Association, should insist, by the adoption of a standing rule, resolution or otherwise, that its officers, during their term of office, refrain from public discussion of broad policies of public welfare, except such as have been officially adopted by their organizations, in order to protect the membership from being committed without an opportunity for expression of opinion. Even if such speakers definitely explain that they speak for themselves alone, they cannot dissociate themselves from their public offices.

The various councils, bureaus and publications of the American Medical Association have been established by the House of Delegates or their creation has been approved by the House. Their progress as reported to you by your Board of Trustees is most gratifying. Their work has increased tremendously year by year and the demands made on them at all times tax their resources. I want merely to mention some of their difficulties—difficulties which it seems to me are quite unnecessary and which tend to defeat their purpose.

Seldom is there a period in organizations so strikingly influential for the future of a profession, and of the public, as was that of 1900 to 1906 in the American Medical Association. The fruits of medical contributions were being jeopardized by the multiple evils which became apparent in the proprietary medical school, in the exploitation of physicians by commercialized directories and in the commercial domination of our therapeutics. History has repeatedly shown that in times of crises leadership arises. So it was under the able leadership of Dr. George H. Simmons, supplemented by the loyal support of progressive physicians, that the period 1900 to 1906 was one of exceedingly constructive efforts, the magnitude of which grows more in the increased perspective of the last thirty years.

The proprietary evil has always been with medicine in one form or another. In America the development of all sorts of so-called ethical preparations began about 1875 and grew to serious proportions at the first part of this century. From time to time the medical profession became articulate against the debasedness of the proprietary medicine evil. The profession was also aware that it had no means of determining those new drugs in which it should have confidence from those which were bad, and in both cases the advertising for them generally teemed with claims preposterous even then. The growing concept of the sad state of materia medica was augmented by a resolution in 1904 from the delegates of the Michigan State Medical Society asking that the Board of Trustees be requested to provide a means whereby analyses of medicinal substances could be made and reports obtained concerning the composition and properties of these substances.

The Council on Pharmacy and Chemistry (the name given the body composed of well known pharmacologists, pharmacists, chemists, clinicians and bacteriologists) was organized Feb. 11, 1905, primarily for the purpose of disseminating information which would protect physicians and the public against fraud, imposition, undesirable secrecy and unwarranted therapeutic claims. The Council has carried on its work for thirty-four years. No one unfamiliar with the work of this Council can appreciate the sacrifices demanded of its members and the indebtedness of this association to them.

Thirty years ago there were no medical journals whose advertising pages could be considered a credit to the medical profession. Today not only the greatest medical journal in the world but the state journals and many independent journals show by their clean advertising the imprint of the Council's efforts in furthering rational therapy and enhancing the scientific treatment of the sick.

In contrast are the pages of certain little magazines sent without subscription charge to all members of the profession —magazines usually referred to as "throw away" journals. Most of the advertising in these journals is not acceptable to the American Medical Association. This of course is the reason for their existence. They have no doubt been extremely profitable to their private owners for they have furnished to these advertisers a large audience which could not be obtained through the American Medical Association journals. One of them has repeatedly attempted to undermine the councils and committees that have attacked nostrums and made therapy scientific. Some publish the names of an "advisory board"—names of leading members of this organization. All publish articles or abstracts written by our members. It is hard to believe that members of this organization will lend their names to the promotion of publications of this type.

A matter of similar interest relates to the journals created by this House to cover the specialties. These are the ranking journals of the world in their special fields. All but three are published at a loss. In competition with them are certain journals published for profit by commercial firms which accept advertising far from meeting the requirements of our Council on Pharmacy and Chemistry. Many of these are excellent journals. Their covers advertise long lists of names of men high in our ranks, while their advertising pages recommend to the reader products these same editorial boards would blush to endorse.

Thirty-five years ago this House created a Council on Medical Education, later to become the Council on Medical Education and Hospitals. As a result of its work there has, during these years, been an unparalleled advance in medical education. No other agency could have accomplished what it has. The activities of this Council have constituted one of the greatest safeguards for the protection of the health of the American people. You will be called on at this meeting to decide important questions on which the future influence of this council will depend. If its work, independence and responsibility are to continue unchanged, we should be able to demand for it the loyal support of every member.

During the past year THE JOURNAL has continued its fearless editorial policy of attack on quackery. These exposés have for years resulted in suits for damages being brought against the Association. We have recently won the suit brought by John R. Brinkley against the editor of *Hygeia*. Many suits never come to trial, but attorneys' fees and preparation for defense entail large sums of expense. We sometimes wonder whether the public is appreciative of this effort and expense in its behalf. Nevertheless we have at all times considered it our duty to expose dishonesty in medicine wherever it is found. Several suits against the Association are pending at this time. We have never compromised and we have never retracted, for we stand firmly on the principles and truths that we enunciate.

It is no secret that these are troublous times. Modern technics for bringing pressure on various groups of our population to obtain favorable action for extraordinary economic and sociologic proposals have resulted in constant harassment of the medical profession. In the midst of these trials come many requests that the Association embark on new projects in the field of research, in the field of publication, in protection of the public against the hazards of unethical practices, in public health education. Many of these suggestions seem highly desirable, and it is the hope of your officers that we may be able to undertake them, at a time not too far away, when stability in economics, in government and in industry shall again prevail.

Finally, may I urge every possible effort to train and educate our members to think of, and refer to, the American Medical Association not in the third person but in the first. Five thirty-five North Dearborn Street is not the American Medical Association. It is a *building*, occupied by more than 600 employees engaged in carrying out the activities and policies this House of Delegates has created. *You* are the American Medical Association. The membership you represent is the American Medical Association. Nothing can come from that building which you have not authorized. A criticism of the American Medical Association, yes, an indictment of the American Medical Association or of any of its officers, is a thrust at you personally and individually.

Unfavorable comment when heard is usually due to ignorance regarding the organization and its activities. I wish every member could visit our headquarters and become familiar with it. Let us urge this on our membership, and, if our state and county societies would delegate certain members to visit it annually, the investment in the expense entailed would yield rich dividends to all concerned.

CONCLUSION

Members of the House of Delegates, throughout my entire professional life I have been associated with the work of the American Medical Association. I recall the giants of American medicine who in the past have arisen in this House of Delegates to defend the ideals and objectives of this great organization. I call to mind Frank Billings leading the

campaign against unethical proprietary medicines; the work of William J. Mayo in advancing the science of surgery; Frank Wynn of Indiana giving impetus to our great scientific exhibit. All of us remember the sagacious leadership of Malcolm LaSalle Harris, the idealism of the distinguished George de Schweinitz, the devotion of Pusey, of Hubert Work, of Richardson and many others. These men, busy in the practice of medicine and with their personal affairs, gave freely of their time and of their lives to advance the progress of organized medicine. They were the builders, in this House of Delegates and in various official bodies, who turned over to us the great institution for which we now carry the responsibility. It is a serious and a sacred trust. The officers whom you have elected, the employees who administer your affairs, look to you for guidance in their work, for support in their activities, and for confidence which will inspire and stimulate them to maintain securely and build more greatly what is already the greatest organization of physicians that the world has ever known. In this House of Delegates there are physicians with knowledge, with astuteness, with abilities equal to those of the great founders and leaders of the past. The times demand the most that you can give. I believe we may depend upon you to rise to the occasion.

During the coming year my resources in time and strength are yours to command. I ask only your full cooperation in all that is best for medicine and for the people of this great country.

Address of the Vice President, Dr. Howard Morrow

The Speaker presented the Vice President, Dr. Howard Morrow, San Francisco, who addressed the House as follows:

Mr. Speaker and Gentlemen:

I am not on the official program, so I will try to give you something impromptu. I was most embarrassed last night when I stood in the hall being photographed with Dr. McCormack of Kentucky. After the photograph was taken the photographer wanted to know from Dr. McCormack who he was. It took Dr. McCormack five minutes to tell him he was President of the Southern Medical Association, the head of the Department of Health of Kentucky, the head of everything in Kentucky. Then he turned to me and said "Who are you?"

I said "My name is Morrow, H. Morrow." "But," he said, "who are you?"

I said, "Nothing, nobody, just a small fry from the Coast."

By that time Morris Fishbein came along and he said "He is supposed to know something about leprosy."

I said "My God! If they put that in the newspaper I'll lose what little practice I have."

Address of Dr. C. E. Hercus

On request of the Chairman, the Secretary presented Dr. C. E. Hercus, Dunedin, New Zealand, who addressed the House as follows:

Mr. Speaker, Dr. West and Members of the House of Delegates:

I thank you very much indeed for the cordial way in which you have welcomed me, a visitor from the most southern of the British dominions. It is a very great privilege indeed to be invited to attend this great meeting of this great Association, and it is a very great privilege and pleasure for me as a representative of the New Zealand and British Medical associations to bring to you their tribute and to thank you for the flow of publications that come from your offices, which have been of greatest value in our British medicine in New Zealand. The many journals which you have sent and which have been referred to this morning have been a source of great inspiration and help to us in the South and we thank you for it. We also wish to pay a tribute, and I as their representative do so now, to this great country and to this great profession for the traditions established and maintained by you which were referred to in that eloquent speech of the Speaker. We in the southern dominions, I think, stand for those same traditions and ideals for which you stand, and we do look to you increasingly for leadership and inspiration.

I thank you very much for your welcome.

Address of Dr. T. C. Routley

The Secretary then presented Dr. T. C. Routley, the secretary of the Canadian Medical Association, who addressed the House as follows:

Mr. Speaker, Mr. President, Mr. President-Elect, Dr. West, Gentlemen:

There is a law up in our country which says that if one has undisputed and undisturbed right of way for a period of twenty-one years, that right of way becomes permanent and irrevocable. Sixteen years ago at your meeting in San Francisco, by the cordiality of your welcome and the affectionate way you treated me during my stay with you, I commenced my right of way into the hearts of the House of Delegates of the American Medical Association. Now, Mr. Speaker, it is my hope that five years from now I shall be able to claim an undisputed and undisturbed right of way in perpetuity.

I, sir, look forward always with the greatest of pleasure to coming to your annual meeting, and I do bring you on this occasion, as I have done on previous occasions, the most affectionate greetings from your brother practitioners north of the 49th parallel of latitude. As I have told you before, we are a very small body numerically but our problems are the same as yours and we do regard you as our big cousin over here, giving us the lead in many directions.

Sir, while on my feet I should like, if I may, to pay tribute to your Secretary, Dr. Olin West, and to his associates who have been so kind to the Canadian Medical Association whenever we have called on them for counsel and advice. Indeed, I couldn't begin to tell you just what it has meant to us from year to year to know that wherever and whenever we needed some assistance Dr. West was always so courteous and so prompt in giving us that assistance.

So I bring you again the greetings of the Canadian Medical Association and I thank you, sir, and this House of Delegates for your kindly reception.

REPORTS OF OFFICERS

Report of the Secretary

Dr. Olin West presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary. Dr. West then announced that since his report had been put into print the membership had increased to 113,113 and the Fellowships to 70,100.

The Secretary then read a telegram of greeting from Dr. Rudolph Matas, New Orleans, recipient of the Distinguished Service Medal in 1938, and announced the receipt of communications from organizations, officials and mercantile establishments in St. Louis, sending greetings to the American Medical Association.

Report of Board of Trustees

Dr. Arthur W. Booth, Chairman, presented the report of the Board of Trustees.

Supplementary Report on Medical Patents

Dr. Roger I. Lee, a member of the Board of Trustees, then presented the following supplementary report of the Board dealing with medical patents:

From time to time the House of Delegates has reaffirmed its position in regard to the undesirability of doctors taking out medical patents. The Judicial Council has given the subject repeated and prolonged consideration and decided not to recommend any changes in the present procedure. The House of Delegates, in a recent meeting, referred the matter of medical patents to the Board of Trustees for report. In consequence of this action, the Board of Trustees appointed a committee to secure further information.

Finally, on March 16, 1939, a conference at the headquarters of the American Medical Association was called, to which all interested parties were invited. At this conference varying points of view were presented by representatives of the Scarlet Fever Committee, Inc., the Insulin Committee of the University of Toronto, of the manufacturers, of the public, and of the Council on Pharmacy and Chemistry. The publication of the

proceedings of this conference has been unavoidably delayed but will appear in THE JOURNAL in a few weeks.

The views presented varied widely. One was that at one end was the view that patents should not be secured in the medical field or that they should be frankly dedicated to the public; another expressed the desirability of securing medical patents and of energetically controlling these patents for the protection of the public.

There were some points of agreement. One was that the attitude of the manufacturers was clearly defined and fair. Again, it seemed clear that if a patent is controlled it will result in much litigation. Moreover, it seemed evident that few medical individuals personally benefited financially from patents. However, it appeared that in some instances there had developed a real competition between the manufacturers, the commissions and the committees directly or indirectly under the control of universities. In some of these instances money in varying amounts accrues to the universities for purposes of research. Furthermore, there was evidence brought out in the conference, as had been brought out in resolutions before the House of Delegates, that there was a real danger of a severe control of a medical patent interfering with medical research.

SUPPLEMENTARY REPORT ON ARMY MEDICAL LIBRARY

Dr. Booth presented the following Supplementary Report of the Board of Trustees pertaining to the Army Medical Library:

The act passed by the Seventy-Fifth Congress authorizing the construction of a new building in which to house the Army Medical Library and Museum, approved by the President June 15, 1938, carried no appropriation for the construction of the building. That session of Congress adjourned without otherwise making available the necessary money. The Seventy-Sixth Congress convened Jan. 3, 1939. Copies of the resolutions adopted by the House of Delegates at the San Francisco session, petitioning the Congress to make available the necessary fund to construct the building as soon as practicable, were promptly forwarded to the President of the United States, the Vice President, the Speaker of the House of Representatives, the Secretary of War, the Chief of Staff of the Army, and the chairmen of the House and Senate Committees on Military Affairs and on Appropriations. The War Department appropriation bill, however, in which the appropriation for the library building would normally be placed, has already passed the House and the Senate but contains no such appropriation, nor is the appropriation proposed in any other pending bill. Our state associations have been urged to petition the Congress for prompt action with respect to this appropriation and to appoint committees to keep constantly in touch with the matter.

The Board suggests that the House of Delegates reemphasize its hope that the necessary fund to construct this building be made available by the Congress without delay as the need is urgent.

SUPPLEMENTARY REPORT ON FEE SCHEDULES

Dr. Booth presented the following supplementary report of the Board dealing with fee schedules:

In response to the request of the House for a report on fee schedules, the Bureau of Medical Economics has given careful consideration to the matter. It is still studying it and simply wants to report progress at this time.

SUPPLEMENTARY REPORT ON WAGNER NATIONAL HEALTH BILL

The Wagner National Health Bill is an important measure. It has received consideration by the Board and that body feels that it should be considered by the House of Delegates. It is suggested that the Speaker appoint a special reference committee to which this bill and any matters that may be presented bearing on it may be referred for consideration.

Dr. Frederic E. Sondern, New York, moved that the suggestion of the Board be adopted and that the Speaker be requested to appoint a special reference committee to consider this bill, the committee to report to the House during the executive session on Tuesday. The motion was seconded by several delegates and carried.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, the Speaker was authorized to appoint a reference committee on executive session.

The Speaker then announced the following personnel of these two reference committees:

CONSIDERATION OF THE WAGNER NATIONAL HEALTH BILL

Walter F. Donaldson, Chairman.....Pennsylvania
Frederic E. Sondern.....New York
Walter E. Vest.....West Virginia
Fred Rankin .....Section on Surgery, General and Abdominal
E. H. Cary.....Texas
Henry A. Luce.....Michigan
Howard L. Snyder.....Kansas

EXECUTIVE SESSION

Charles J. Whalen, Chairman.....Illinois
Herbert L. Bryans.....Florida
H. G. Hamer.....Indiana
John M. Birnie...
Peter Irving .....
Clyde L. Commer.
McLain Rogers.....Oklahoma

The report of the Board of Trustees and its supplementary reports were then referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the exception of the Supplementary Report on Medical Patents, which was referred to the Reference Committee on Legislation and Public Relations and the Supplementary Report on the Wagner National Health Bill, which was referred to the Reference Committee on Consideration of the Wagner National Health Bill.

Supplementary Report of Board of Trustees

REPORT OF COMMITTEE TO STUDY PROBLEMS OF MOTOR VEHICLE ACCIDENTS

The Secretary presented the following report of the Committee to Study Problems of Motor Vehicle Accidents, which was referred to the Reference Committee on Legislation and Public Relations:

The Committee to Study Problems of Motor Vehicle Accidents met at the headquarters of the American Medical Association on Dec. 8, 1938. Those attending were Dr. Herman A. Heise, Milwaukee, Chairman; Drs. Burt R. Shurly, Detroit, and C. W. Roberts, Atlanta, Ga., members of the committee; Mr. J. S. Baker of the National Safety Council, and Dr. Olin West, Secretary of the American Medical Association.[1]

The members of the committee are aware of the marked reduction in motor vehicle accidents and fatalities since the peak year of 1937 and are convinced that the improvement is due chiefly to education and traffic law enforcement. The medical profession realizes its responsibility and believes that further improvement can be obtained if the following facts are comprehended and the recommendations set forth here are adopted.

PHYSICAL AND MENTAL DEFECTS

Physical and mental defects, as they affect motor vehicle accidents, can be classified roughly into three general groups according to the duration of the disability:

1. Permanent deficiencies, such as missing extremities, certain visual and hearing defects, feeblemindedness, and small stature.

2. Transitory deficiencies which may impair ability for a number of days or months, such as weakness during or after illness, arthritis, various diseases which may cause coma or seizures, and mental troubles which may result in unstable emotional states.

3. Brief and often self-inflicted disabilities from which recovery is usually natural, certain, complete and prompt, such as intoxication, the effect of drugs, lack of sleep, unusual excitement or worry.

Official agencies for dealing with physical and mental defects as they relate to driving ability include drivers' license administrators and city and state police departments. The drivers' license administrators watch for the more obvious permanent physical defects when they examine new drivers for licenses. They also conduct hearings and reexamine those drivers who

1. The Chairman was assisted in the preparation of this report by the secretaries and other members of the National Safety Council's Committee on the Driver and Committee on Tests for Intoxication. The statements and recommendations set forth here are substantially concurred in by these two committees of the National Safety Council.

have had more than their share of traffic accidents or traffic violations, to determine whether the licenses should be suspended or revoked. The police officials deal primarily with the drivers who get into trouble because of temporary disabilities such as intoxication.

There are many problems in determining minimal physical and mental standards for new drivers. Higher qualifications may be set for the employment of commercial drivers than for the licensing of the general public, because the former involves a process of selecting the few best from many, and any questionable applicant may be rejected, whereas, in licensing the public, only the *certainly unfit* may be rejected and all questionable applicants must be given the benefit of the doubt and accepted.

Loss or paralysis of limbs is not as dangerous as it might be, because the automobile may be especially equipped for drivers so afflicted and because such drivers usually compensate by extra care. The problem in dealing with sensory defects is one of establishing the point in deficiency at which the hazards become great enough to bar the person from driving; much research is yet needed to determine standards for sensory defects. The dangers of low intelligence are not generally realized, and as yet little has been done either to set standards of intelligence for drivers or to relate mental development to possible hazards.

Certain mental and physical defects are evident even in childhood. If it were possible for the schools to keep simple records which would follow the progress of a child through school, information could be gathered which would be very valuable when this individual applies for a driver's license. Such a record should include notations as to serious eye and ear defects, epileptic seizures, and so on. Also records of unstable individuals of low intelligence (I. Q. less than 70 per cent) would be of value. More careful examination of persons with bad school records would aid materially in keeping the potential accident-prone person off the highways.

Suspension and Revocation of Driving Privilege.—It is a well known fact that a small percentage of drivers are involved in more than their share of traffic accidents and have more than their share of traffic violations. It is of the utmost importance that adequate records of traffic accidents and major traffic violations be kept so that these persons can be identified and reexamined to determine whether they should continue to have the privilege to drive. Such records should preferably be kept by a state department and should be readily available to similar departments in other states. Persons having had more than their share of accidents or violations should be given special examinations, and hearings should be conducted to determine whether their licenses should be suspended or revoked.

Transitory Deficiencies.—These deficiencies ordinarily cannot be brought to light by original examination for licenses because they may develop at any subsequent time. Most of them would even escape detection in any practical periodic reexamination. However, most such conditions call for medical attention and thus come to the notice of physicians.

Probably the greatest contribution to traffic safety that the medical profession as a whole can make is in preventing accidents due to transitory disabilities. It should be the duty of physicians to inform patients of the possibility of prescribed drugs causing driving hazards. This applies particularly to insulin, opium derivatives and other sedatives. The use of anesthetics for minor operations may also leave the patient in the condition in which he is less able to cope with traffic. Too many drivers, during investigations of accidents in which they were involved, attribute the mishaps to dizziness, faintness, sickness or weakness "because of something the doctor gave me," or because of a condition for which they were under treatment.

ALCOHOLIC INTOXICATION

The importance of alcohol as a factor in traffic accidents has been demonstrated further by the work of Holcomb[2] in Evanston, Ill. Alcohol tests were made of the breath of 1,750 drivers chosen at random on the streets of Evanston, a legally dry community, and results were compared with the results of alcohol tests made on the urines of 270 drivers brought to Evanston hospitals after being involved in personal injury accidents. If alcohol were not a factor in accidents, it is obvious that the percentage of drivers in each of these two groups who had been drinking would be about the same. However, it was found that 47 per cent of those involved in personal injury accidents had alcohol in their blood, while only 12 per cent of the drivers selected at random were in the drinking class. The results are even more significant when a comparison is made of the percentages of drivers in each class whose blood contained 0.15 per cent of alcohol or more. Assuming that the chance of having an accident when no alcohol has been consumed is represented by the number one, then the chance of having an accident has been shown to be fifty-five times greater when the average person has a concentration of alcohol in his blood of 0.15 per cent or more. (Approximation by Committee on Tests for Intoxication, National Safety Council, in its 1938 Report.)

Holcomb's survey confirms previous observations that alcoholic intoxication contributes materially to the peak of accidents, which occurs on Saturdays and Sundays. His study also confirms the belief of many that alcoholic intoxication, rather than darkness, is the major cause of the high proportion of personal injury accidents in the hours after midnight.

The concentration of alcohol in the blood is one of the best criteria of intoxication because blood alcohol concentrations closely parallel detrimental effects noted in carefully conducted experimental tests. Although this relationship is not mathematically exact because of slight variations resulting from inherent differences in human beings, it is sufficiently accurate for practical purposes. The relationships between concentrations of alcohol in blood, urine, saliva and breath have been shown to be sufficiently definite so that chemical tests of any of these body materials can furnish a reliable measure of the degree of alcoholic influence.

For medicolegal purposes, the committee recommends the following interpretation of chemical tests for alcohol:

1. Although there is no minimal figure which can be set at which there will be absolutely no effect from alcohol, the committee recommends that persons with a concentration of alcohol of less than 0.05 per cent by weight in blood or its equivalent in urine, saliva or breath should not be prosecuted for driving while under the influence of alcoholic liquor.
2. All persons show a definite loss of that clearness of intellect and control of themselves which they would ordinarily possess when the concentrations are above 0.15 per cent in the blood or its equivalent in other body fluids or breath and should therefore be considered as under the influence.
3. When the alcohol concentrations are between 0.05 and 0.15 per cent in the blood, a great many of the persons will be under the influence of alcohol, but the committee recommends prosecution only when the circumstances and results of physical examination give definite confirmation of such influence.

Chemical tests for intoxication are compulsory in Sweden and Germany after traffic accidents. These tests are used also in a number of other European countries. Results of chemical tests have been used as evidence in court in at least fourteen states in this country. Indiana is the first state to adopt a law which defines borderline limits for alcoholic influence in terms of amount of alcohol in the defendant's blood. The limits set forth in this law conform essentially with those recommended in this report.

Results of chemical tests of specimens which are obtained without compulsion and properly identified are almost always admitted as evidence in courts in this country. Chemical tests are usually employed to corroborate evidence obtained from observation of the accused. In cases involving injury from an accident, the evidence from chemical tests eliminates guesswork, even though the suspect is unconscious or displays symptoms which may be the result of injuries sustained in the accident.

The tests exonerate the innocent as well as assist in convicting the guilty. Cities using chemical tests obtain a much higher proportion of guilty pleas and a much higher percentage of convictions of cases which go to trial. Use of chemical tests enable the prosecution to refute the usual "two bottles of beer" defense.

When the defendant pleads guilty, it is not necessary to have an expert testify on the relationship between concentrations of alcohol in body materials and the probable degree of alcoholic

2. Holcomb, R. L.: Alcohol in Relation to Traffic Accidents, J. A. M. A. **111**: 1076 (Sept. 17) 1938.

influence. However, this expert testimony is necessary in all court cases in which the admissibility of chemical test evidence is questioned by the defense attorney. Physicians are often called on to give expert testimony on the meaning of the test results. Before attempting to present such expert testimony, physicians should become familiar with the literature on the subject and should preferably have some experimental background on the relationship between physical impairment and test results.

In some states, courts will refuse to admit testimony of physicians who have treated an injured person at the time a physical examination is made or a specimen is obtained for chemical tests, holding that the treatment creates a physician-patient privilege. When there is a possibility of such a privileged relationship developing, the specimens for chemical tests should be taken by other persons.

The medical profession is particularly fortunate in having these chemical tests at its disposal. They will enable the profession to avoid the well known "disagreements of experts." Their use is recommended whenever physicians are called on to diagnose degree of alcoholic influence for city and state enforcement departments.

Respectfully submitted.

Report of the Judicial Council

Dr. George Edward Follansbee, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Reports of Officers.

Report of the Council on Medical Education and Hospitals

Dr. W. D. Cutter, Secretary of the Council, presented the report of the Council on Medical Education and Hospitals as printed in the Handbook, together with the following supplementary report, which was referred to the Reference Committee on Medical Education:

Supplementary Report

First, the report on the survey of medical and hospital care in the state of Mississippi, referred to in paragraph 6 of the Council's report to the House of Delegates (page 176 of the Handbook), was not completed in time for distribution to the members of the House of Delegates. It will be printed in The Journal for June 3. A brief abstract of this report is presented to the House of Delegates.

Second, since the publication of the Essentials of a Registered Hospital, page 178 of the Handbook, those sections dealing with the physical plant, medical staff organization, pathology and laboratory diagnosis, anesthesia, and dietetics have been amplified. These revisions are submitted to the House of Delegates as a part of this supplementary report.

Third, The Essentials of an Approved Examining Board in Specialties, page 202 of the Handbook, were further revised at a meeting of the Council on May 14. Section III, paragraph A, subheading 3, was amended to read "Membership in the American Medical Association is recommended."

Fourth, The Council has found it desirable to confer with the examining boards in several of the specialties and some of the special societies, such as the American College of Physicians and the American Psychiatric Association, concerning problems of graduate medical education relating to the training of specialists, and requests the permission of the House of Delegates to explore the possibility of cooperative relationships with such organizations.

Ray Lyman Wilbur, Chairman.

William D. Cutter, Secretary.

Survey of Hospitals and Medical Care in Mississippi

The state of Mississippi was selected by the Council on Medical Education and Hospitals for a complete study of hospitalization and facilities for medical care. The procedure involved personal visits of inspection by members of the Council's staff to all the hospitals, registered and unregistered. The state health department and a number of county health departments lent their cooperation in supplying data for the survey. The number of hospitals, related institutions and unclassified facilities inspected for the survey totaled 117.

1. In appraising medical service in this state, one must take into account the fact that more than 50 per cent of the population in Mississippi are Negroes and that the demand for medical service among this group may fall below the requirements of the white population.

2. While the population is approximately equally divided, the number of general hospital beds for Negroes is 0.7 per thousand as compared with 2.4 per thousand of the whites. Although the proprietary hospitals are most numerous as a group, they control only 12.1 per cent of the beds. All available information clearly points to the fact that additional general hospital beds are not needed for the white population in Mississippi, the percentage of unoccupied beds being 46.8 per cent. Distance and transportation offer no serious difficulties. Four small areas in the state are more than 30 miles from a hospital, but these districts are well served by the hospitals in urban centers. Approximately 25 per cent of the patients admitted to all general hospitals came from a distance of 30 miles or more. It is not uncommon for patients to travel upward of 70 miles to the hospital of their choice.

3. The tuberculosis program is in need of more adequate financial support in order to utilize the present facilities and to increase the number of beds about 100 per cent.

4. The number of beds for nervous and mental patients is apparently adequate for the needs of the state. A field psychiatric clinic program, however, is needed.

5. Mississippi has no hospitals approved for intern or residency training. Several have made application and are now in the process of conforming to the requirements.

6. Obstetric delivery rooms and nurseries are needed in many general hospitals offering this service; thirty-seven have no delivery rooms and forty-three have no nurseries.

7. More qualified radiologists and pathologists are needed in the state. Clinical laboratory facilities do not provide a sufficiently wide scope of service in most hospitals. Investigation indicated that clinical laboratory examinations should be more complete.

8. The development of nursing education in Mississippi has not kept pace with the advances in other parts of the country and this may be partially ascribed to economic conditions. The number of graduate nurses employed in general hospitals does not compare favorably with accepted standards of hospital service.

9. It appears that the distribution of physicians in Mississippi has followed the general trend away from rural areas, but this does not necessarily mean a lack of sufficient medical service. Other factors tend to enlarge the territory which a doctor can serve, such as better communications, better methods of transportation, improved roads, and hospital facilities.

10. Extensive inquiry among all classes of the population, including doctors, workers, health officers and nurses elicited the almost uniform response that there is practically no person in Mississippi who cannot secure the services of a physician regardless of ability or inability to pay.

Note.—A complete report of the Mississippi survey will be published in The Journal for June 3 and reprints will be available later.

Essentials of a Registered Hospital

General Statement.—Hospitals should be organized and conducted primarily for the purpose of providing facilities where the sick and the injured of the community may be given scientific and ethical medical care.

Registration is a basic distinction between all recognized hospitals and those that are refused recognition. It is a prerequisite to the consideration of a hospital for approval for interns or for residencies in specialties.

The registration of hospitals, the approval of hospitals for interns, approval for residencies in specialties, and all other service of the Association regarding hospitals is carried on by the Council on Medical Education and Hospitals. Separate essentials have been adopted for each of these types of approval.

It is the desire of the Council to cooperate in every way for the improvement of hospital service, whereby the sick and injured may be provided with scientific and ethical medical care.

The Council does not have nor does it assume legal authority over any hospital. It recognizes clearly that the officers in charge of such institutions have the unquestioned right to conduct the hospitals in any way they may deem wise. If a hospital desires to have its name appear on the American Medical Association Hospital Register and thus have the endorsement of that Association, it should be willing to comply with the principles which the Council on Medical Education and Hospitals considers necessary.

I. *Organization.*—1. The organization should consist of a supreme governing body qualified to administer a hospital. This may be a board of trustees or directors, a partnership or an individual. Such a board, partnership or individual must assume final authority and responsibility for the administration.

2. There must be a well qualified executive officer who may be designated as administrator, superintendent or director or by some other title. This person should be responsible to the governing body for carrying out its policies. The executive officer should be assisted by competent personnel adequate to the needs of the institution.

II. *Physical Plant.*—1. The hospital plant should consist of modern, safe buildings maintained in a sanitary condition, provided with fire protection and adequately equipped and furnished for the comfort of patients. Equipment for diagnosis and treatment should be reasonably complete for all types of work the staff purports to carry on in the hospital.

2. Institutions accepting surgical and obstetric patients should provide a modernly equipped operating room, a delivery room and a nursery. Hospitals that are strictly limited in the service they offer are not expected to have the complete organization and equipment of a general hospital.

III. *Medical Staff.*—1. Since the medical staff is the most important factor in the delivery of medical service to patients, too great care cannot be exercised in the selection of staff members. The staff should be limited to physicians holding the degree of doctor of medicine from medical colleges acceptable to the Council on Medical Education and Hospitals, having satisfactory qualifications as to training, licensure and ethical standing, and to dentists who are graduates of recognized dental colleges and whose professional ability and standing are known to the medical staff.

2. Osteopaths, chiropractors and other cult practitioners outside the scope of regular medicine, or unethical physicians, may not be permitted to use the hospital's facilities. They may not enter data on the records, carry out diagnostic procedures or treatments, or in any way assist in doing this work.

3. The form of organization of the staff is determined by the size and the activity of the hospital in accordance with its needs.

4. In very small hospitals where there are few physicians and where an elaborate organization is not practicable, there should still be some authority competent to pass upon the qualifications of those who seek to use the hospital's facilities. Particular care should be exercised in the assignment of surgical privileges since it is essential for the safety of patients that both the surgeon and his assistants be properly qualified.

5. Where further organization is needed it should consist of such officers as president, secretary and others; and committees, such as executive, medical records and credentials, elected or appointed according to the constitution and by-laws.

6. Staff departments such as medicine, obstetrics and surgery, should be organized as may seem wise.

7. Regular staff meetings should be held monthly. The agenda should include:

(a) *Business*
Reading of minutes, unfinished and new business; reports of committees, and so on.

(b) *Medical*
Report of the medical records department; analysis of the work of the hospital; discussion of deaths, infections, complications and consultations.
Reports of standing and of special medical committees.
Discussion and recommendations for improvement of the professional work of the hospital.

Postmortem examinations that have been performed should be presented together with the clinical aspects. Pathologic specimens removed surgically or at postmortem may be demonstrated and discussed.

8. Minutes of all staff meetings and attendance records shall be kept by the secretary.

IV. *Pathology and Laboratory Diagnosis.*—1. The laboratory facilities should provide as complete a service as is practicable.

2. The pathologist should preferably be a physician who holds the certificate of the American Board of Pathology. Where it is not possible to employ the services of a pathologist directly, arrangements should be made for a consulting service for tissues, postmortem examinations and the interpretation of the more difficult tests and examinations in clinical pathology. All surgical tissues should be examined, described and diagnosed by a pathologist.

3. The department should be equipped for all routine procedures and for whatever additional tests and examinations are frequently called for by the staff.

4. At least one well trained clinical laboratory technician should be employed.

5. Reports of all work done in the department should be kept on file.

6. *Autopsies.*—Every effort should be made to secure consent for the performance of autopsies. They should be conducted by a qualified pathologist or under his supervision, and protocols, including clinical summaries, should always be filed.

V. *Radiology.*—1. The responsibility for all radiologic examinations must rest on the physician-roentgenologist who is head of the department. His findings and conclusions for all examinations should be placed in the patient's chart. Nothing in this provision should preclude additional study and interpretations by qualified attending physicians on the staff.

2. The physician-roentgenologist should be preferably one who is a diplomate of the American Board of Radiology or a physician whose qualifications are acceptable to the Council on Medical Education and Hospitals of the American Medical Association.

3. It shall not be the policy of the hospital to make a profit from the department of radiology.

VI. *Anesthesia.*—The anesthesia service should be under the direction of competent medical personnel whenever possible. If a qualified specialist in anesthesiology is not available, supervision may be assigned to some member of the staff who has had special training in this field or to a nurse anesthetist whose qualifications are acceptable.

VII. *Nursing Service.*—1. A competent nursing service should be provided, adequate for complete coverage for both day and night periods, and for surgical and obstetric supervision. All nursing should be supervised by registered graduates. Hospitals that do general surgery should have a trained operating room nurse.

2. *Dietetics.*—The services of one or more graduate dietitians, as may be required, should be available for supervision of regular and special food services. Where graduates cannot be employed, these functions should be assumed by some competent person.

VIII. *Pharmacy.*—The handling of drugs should be properly supervised and should comply with all the legal regulations. Accurate records should be maintained. A qualified person should be placed in charge, preferably a graduate pharmacist; whatever arrangement is made, all prescriptions should be filled by a graduate pharmacist.

IX. *Medical Records.*—1. An adequate record system should be maintained in all departments. No certain forms are recommended since requirements vary greatly according to the size and type of hospital. Samples of suitable forms for all departments may be readily obtained from publishers of hospital records.

2. Case histories and physical examinations should be recorded immediately following the patient's admission. In no case should it be longer than twenty-four hours after admission. The history, physical examination, routine laboratory work and provisional diagnosis should be recorded before an operation except in emergencies. The attending physician is directly responsible for the accuracy and completeness of case records, whether prepared by him or by another.

3. The usual case record consists of identification data, chief complaint, past medical history, family history, history of present illness, physical examination, provisional diagnosis; special reports such as consultations, clinical laboratory, pathology, x-ray and the like; medical or surgical treatment, progress notes, final diagnosis, condition on discharge and follow-up records; autopsy report when available.

4. No case record should be filed until it is complete and then only after it has been reviewed and signed by the attending physician.

5. Monthly and annual analyses of hospital service should be made in order that the staff may be in a position to improve its service.

X. *Ethics.*—In order that a hospital may be eligible for registration it will, of course, be expected that the staff and management conform to the principles of medical ethics of the American Medical Association with regard to advertising, commissions, division of fees, secret remedies, extravagant claims, overcommercialization and in all other respects.

Report of the Council on Scientific Assembly

Dr. James E. Paullin, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

Dr. Paullin added that the members of the Council record with deepest regret and sorrow the loss by death of one of their members, Dr. J. C. Flippin, Charlottesville, Va.

Presentation of New Members

The Speaker read the names of members of the House who had never served in the House previously and requested each one to stand to be recognized when his name was called.

NEW BUSINESS

Resolution on Granting a Seat in the House of Delegates to a Woman Delegate

Dr. Floyd S. Winslow, New York, in behalf of the Medical Society of the State of New York, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, It is a critical time in the history of American medicine, when it is important that all physicians should unite in safeguarding the interests of the profession; and

WHEREAS, The American Medical Association especially needs at this time the active interest and loyal support of all its members; and

WHEREAS, There are about 8,000 to 9,000 women physicians in the United States, many of them eligible for membership in the American Medical Association and many of them already members thereof; and

WHEREAS, These women physicians have in many states organized city and state associations; and

WHEREAS, There is also a national organization known as the American Medical Women's Association, the members of which have found it difficult to build a powerful organization because of the relatively few women and lack of large funds; and

WHEREAS, It is undesirable to segregate the women physicians' interests from the interests of the profession as a whole; and

WHEREAS, The ratio of women physicians to men physicians is so small that the chance of representation in the house of delegates of the various state medical societies is almost nil; and

WHEREAS, We believe that the women's medical organizations have much to give in big visioned ideas, vigorous work and loyalty if their wishes can only be made articulate; therefore be it

Resolved, That the House of Delegates of the American Medical Association grant a seat to a woman delegate.

Resolution on Testing of School Children for Early Detection of Defective Vision and Hearing

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Thousands of children with defective vision and hearing in the schools of our country are endeavoring to obtain an education; and

WHEREAS, The importance of the early diagnosis and correction of these defects is necessary to better education; be it

Resolved, That the American Medical Association give support and encouragement to the various state medical societies and other agencies and foundations in carrying on a nation-wide testing of school children for the early detection of these handicaps.

Resolution Urging that Membership in the American Medical Association Be Not Denied Solely on Basis of Race, Color or Creed

Dr. James M. Flynn, New York, in behalf of the Medical Society of the State of New York, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, A rapidly changing social order is demanding a reorientation of the attitudes and responsibilities of the individuals and agencies engaged in providing for the medical care of the public;

WHEREAS, The entire strength of all elements engaged in the practice of medicine should present a united front in facing and solving these problems in the interest of the public health;

WHEREAS, The Negro physicians numbering more than 5,000 in the United States and about 350 in New York State bear the direct responsibility for the care of approximately 13 million citizens whose collective health problems form one of the most challenging areas in the entire battle-line against sickness and disease;

WHEREAS, These physicians have not only demonstrated individually and collectively their ethical and professional fitness to shoulder their just responsibilities but have shown a zeal and a devotion to the health problems of their people worthy of the best traditions of American medicine;

WHEREAS, The best interests of the entire medical profession and, indeed, of the entire public demand that they receive identical opportunity for medical education, for professional experience in hospital and clinic and for participation in public health programs, public and private—in short, all of the rights, privileges and responsibilities inherent in regular membership in organized medicine;

WHEREAS, The county medical society is the basic unit of the American Medical Association, membership in which is a prerequisite for membership in the American Medical Association;

WHEREAS, South of the Mason and Dixon line, Negro physicians are generally and systematically excluded from membership in county medical societies, making membership in the American Medical Association and affiliation with organized medicine impossible;

WHEREAS, This exclusion along racial lines strikes at the fundamental rights of this large group of physicians and indirectly lowers the quality of medical care which they must deliver to an already underprivileged group whose health problems admittedly press more firmly for solution than those of any other racial group;

WHEREAS, These Negro physicians have time and again demonstrated their constancy and heroic devotion to the democratic form of government and all that that term implies and have strongly recorded their position toward the pending medico-economic issues as identical with that of organized medicine; and

WHEREAS, The Medical Society of the State of New York has, through its House of Delegates, recorded as its considered opinion that any and all restrictions imposed on any American citizen solely on the basis of race or religion is not only inimical to the cause of the public health with which we are so deeply concerned but dangerous to the entire body politic of our democratic form of government; and

WHEREAS, The Medical Society of the State of New York, in keeping with this opinion, has urged its members, especially those in positions of key responsibility in education, and in charitable and public health enterprises, such as medical schools, hospitals and clinics, to consider seriously the removal of any restrictions not only as a matter of simple justice but in the light of their inherent capacity to hamper and restrict the entire medical profession in rendering the best possible service to the public and use their good offices and influence in removing any restrictions based solely on race or religion, to the end that our proud boast of a truly democratic form of government, a truly liberal and unselfish medical profession, be less honored in the breach than in the observance; therefore be it

Resolved, That the House of Delegates of the American Medical Association declare its belief that membership in the various component county societies of the American Medical Association should not be denied to any person solely on the basis of race, color or creed.

Resolution Limiting Directorship of Approved Clinical Laboratory to Licensed Physician

Dr. Frederic E. Sondern, New York, presented the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, Years ago the examinations made by clinical laboratories were largely factual in nature and, as a consequence, a portion of the work was done by chemists and technicians not having medical degrees or being licensed to practice medicine;

WHEREAS, Particularly in the last one or two decades, the developments in laboratory medicine have been such as to require clinical medical knowledge for the safe performance of many of the newer diagnostic procedures undertaken; and

WHEREAS, Specimens are obtained by surgical means from the spinal canal, veins and organs of the body, and drugs and dyes are injected for the purpose of various functional tests, all definitely requiring clinical medical experience and judgment for their performance and interpretation if the safety of the patient is to be guarded; therefore be it

Resolved, That only a licensed physician duly qualified as a clinical pathologist may serve as the director of an approved clinical laboratory, as such practice is a specialty of medicine.

Resolutions on Exhibition of Medical or Surgical Procedure to Lay Groups

Dr. Charles B. Reed, Illinois, presented the following resolutions, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws and to the Judicial Council as a reference committee:

WHEREAS, In the Principles of Medical Ethics Chapter III, Article I, Sec. 4, it is stated that the "Solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional," and, further, that it is unprofessional to solicit patients "by indirect advertisement" or "to employ any methods to gain the attention of the public for the purpose of obtaining patients"; and

WHEREAS, The exhibitors of films portraying the physical process of childbirth and other surgical measures to lay groups by individuals, hospitals and commercial concerns are constantly increasing in numbers and in extent of distribution; and

WHEREAS, These pictures, while officially exploited as educational in character, are in reality utilized for the advertisement of individuals, hospitals and commercial products; therefore be it

Resolved, That the exhibition of any medical or surgical procedure to lay groups shall first be approved for that purpose by exhibition of the film to the county or state society where the proposed exhibition is to occur or to a board of censors thereof or to the American Medical Association; and be it further,

Resolved, That exhibitors violating the provisions of this resolution shall be considered unethical.

Resolutions on Wagner National Health Bill

Dr. Fred Moore, Iowa, in behalf of the Iowa State Medical Society, presented the following resolutions, which were referred to the Reference Committee on Consideration of the Wagner Bill:

WHEREAS, The Wagner bill (S. 1620) of the Seventy-Sixth Congress, entitled the National Health Act, in that part pertaining to maternal and child welfare gives the Children's Bureau as a federal administration agency such broad powers (1) in rules and regulations, (2) in setting up undefined advisory councils for participating states, and (3) in determining amount of funds needed after 1942 without limit; and

WHEREAS, The bill makes specific provision for construction of new hospital and treatment centers up to $158,000,000 within three years; and

WHEREAS, The bill does not provide any method or means of determining needs for development of the various services; and

WHEREAS, The bill makes no provision for use of existing unused hospital and treatment facilities; and

WHEREAS, State programs for medical care under this bill are to be subject only to the approval of the Social Security Board; and

WHEREAS, The bill provides that the Social Security Board shall set up state advisory boards whose personnel and responsibility are not defined; and

WHEREAS, The bill makes no specific distinction between medical care for the indigent and that for self-sustaining people, except to stress the need for those in "severe economic distress"; and

WHEREAS, The implications and interpretation of the bill with reference to compulsory health insurance under supervision of governmental units are not clear; therefore be it

Resolved, By the Iowa State Medical Society that S. 1620 will not promote the public interest in economics or health; and be it further

Resolved, That the Committee on Public Policy and Legislation of the Iowa State Medical Society shall request members of Congress from Iowa to obtain modification of the bill in accordance with previously declared policies of the American Medical Association and the Iowa State Medical Society, and, in event of failure in that, to oppose the act; and be it further

Resolved, That the delegates to the American Medical Association present copies of this resolution to that body, with the request that the American Medical Association use its utmost influence to attain these objectives.

Resolution on Medical Care to the Indigent

Dr. Walter B. Martin, Virginia, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, The American Medical Association recognizes the importance of extending more adequate medical care to the indigent and to the low income group; and

WHEREAS, Many plans have been proposed and are being urged that have for their purpose the extension of such care; and

WHEREAS, We believe that many of these plans are unsound in their conception and will not result in the provision of a high quality of medical service to the groups they propose to help, and, further, that they are economically dangerous and extravagant and will result in wasteful dissipation of public funds; and

WHEREAS, The present day cost of medical care is principally due to the vast increase in the accessories of medicine resulting from the rapid progress of the science of medicine during the past generation; and

WHEREAS, Among the seriously ill who incur large expenses as a result of illness the hospital cost constitutes over half of the total cost of their illness; therefore be it

Resolved, That we favor the following plan as the first step in extending more and better medical care to the indigent and the medically needy on a sound professional and economic basis:

1. Payment to the hospital by the government, local, state and federal, of the full cost of hospital care of all indigent patients.

2. Subsidy for the full hospital care of the low income group, this subsidy to be applied through local hospital service associations now existing or to be formed, so as to allow the sale of hospital service contracts at a reduced rate to the low income group below a certain fixed income level.

Advantages:

1. Increased bed occupancy on a pay basis and full utilization of existing facilities.

2. Increased income to hospitals enabling them to (*a*) lower the rates to patients who pay their own way, (*b*) improve their service and facilities and (*c*) set up reserves for needed expansion.

3. Make possible in areas where the medical need exists the establishment of new hospitals which heretofore have not been economically feasible.

4. Improve the standards and quality of hospital service. As payment would be made on the basis of hospital cost and as the cost would vary with the quality of service rendered, there would be a constant incentive to improve facilities and service and thus become eligible to enter a higher income bracket.

5. Make possible the improvement of outpatient service for the ambulatory indigent and the establishment of such service where it does not now exist.

6. Average the principal item of cost in severe illness and reduce the premiums that the individuals in the low income group will pay to approximately $3 to $5 a year.

Cost: It is proposed that half of the cost of this plan be borne by the federal government and half by the state and local governments. Allowing a hospitalization rate of one day for each person each year and an average hospital cost of $5 a day, and accepting the figure of 40 million as constituting the indigent and low income group, the total cost would be from 150 to 200 million dollars. The share of the federal government in such a project would be from 75 to 100 million dollars, which is somewhat less than the expenditures proposed for the first year under the Wagner act.

Resolutions on Rearrangement and Rewording of Principles of Medical Ethics

Dr. E. J. Best, California, presented the following resolutions, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws sitting with the Judicial Council:

WHEREAS, In these and other troublous times in order to maintain the high quality and ideals of our medical profession it is most essential to uphold the standards of the Principles of Medical Ethics without compromise; and

WHEREAS, Since the Principles of Medical Ethics were rewritten in 1912 there have arisen many problems not known to the leaders of our profession twenty-seven years ago; and

WHEREAS, Because of the nation-wide influence of members of component societies who have made presentations on public platforms, in the press and over the radio because of the arrangement and wording of the Principles of Medical Ethics, component county medical societies have recently found it next to impossible to draw up sound charges to discipline members who have violated our medical ethics; therefore be it

Resolved, That the Speaker of this House of Delegates appoint a committee of five Fellows of the American Medical Association to study the Principles of Medical Ethics and the form of the code of ethics of the legal profession, having in mind the rearrangement of our Principles of Medical Ethics for continuity, the rewording for clarity, the addition of a commentary following each principle to illustrate the intent and the quoting of relating decisions of the Judicial Council; and be it further

Resolved, That this committee be directed to report its recommendations to the 1940 session of the House of Delegates of the American Medical Association.

Resolutions Expressing Appreciation of Staff at Headquarters

Dr. E. H. Skinner, Section on Radiology, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

WHEREAS, The medical profession of America has been confronted with vital issues affecting the welfare of all citizens and the free integrity of medicine and calling for courageous leadership and positive action by the organized profession; and

WHEREAS, This action and leadership has been maintained through a loyal and competent headquarters staff; and

WHEREAS, The Council on Medical Education and Hospitals, the Bureau of Medical Economics and other departments in the headquarters office have helped materially in the efforts of radiologists to maintain and raise the standards of radiologic practice, through which efforts definite progress in the gradual solution of some of our vexing problems has been achieved, thereby protecting medicine against insidious harm to one of its parts; *therefore be it*

Resolved, That the Section on Radiology expresses its appreciation and commendation of the members of the headquarters staff for their cordial assistance to the Intersociety Committee for Radiology, as representative of all radiologists, and to this section in upholding and applying accepted principles to assure the continued advancement of radiologic practice and the protection of the science against adverse influences; and be it further

Resolved, That a copy of these resolutions be spread on the minutes of this section of the House of Delegates.

Supplementary Report of Board of Trustees

The Secretary, at the request of the Board of Trustees, presented, as representative of a number of communications that have come to the offices of the American Medical Association, the following communication, which was referred to the Reference Committee on Miscellaneous Business:

THE EPISCOPAL DIOCESE OF WESTERN MICHIGAN
DEPARTMENT OF CHRISTIAN SOCIAL RELATIONS

The Reverend H. Ralph Higgins, S.T.D., Chairman
St. Mark's Church, Grand Rapids, Michigan

April 6, 1939

Dr. Olin West, Secretary
American Medical Association
535 North Dearborn Street
Chicago, Illinois

Dear Dr. West:

I am directed by the Department of Christian Social Relations of the Diocese of Western Michigan to notify you of the Department's endorsement of the recent stand of the American Medical Association in reference to proposed programs of federalized medicine.

The resolution of our department states specifically:

1. We approve the general principles outlined for the expansion of public health and maternal and child health services.

2. We favor the expansion of general hospital facilities where the need exists.

3. We recognize the principle that the complete medical care of the indigent is a responsibility of the community and that such care should be organized by local governments and supported by tax funds; that in poorer communities federal funds may be needed to make up for local inability to raise funds.

4. We are completely unwilling to foster any system of compulsory health insurance or a system of tax supported federalized medicine for the whole population.

5. We approve the principle of hospital group insurance on a nonprofit basis. We endorse the principle of compensation for loss of wages due to illness as put forth under Recommendation V by the Interdepartmental Committee.

This department is an official agency of the Episcopal Diocese of Western Michigan and it is composed of some thirty or forty representatives of the parishes and missions of the Diocese.

Faithfully yours,
H. RALPH HIGGINS

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by several delegates and carried, the House recessed at 1:10 p. m., to reconvene Tuesday, May 16, at 9:30 a. m.

Second Meeting—Tuesday Morning, May 16

The House of Delegates was called to order at 9:45 a. m. by the Speaker, Dr. H. H. Shoulders.

Report of Reference Committee on Credentials

Dr. Deering G. Smith, Chairman, reported that 168 delegates had registered and been seated.

Roll Call

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, the House voted to have the report of the Reference Committee on Credentials constitute the roll call of the House.

Report of Reference Committee on Sections and Section Work

Dr. George Gray Ward, Chairman, presented the following report, which was adopted on motion of Dr. Ward, seconded by Dr. A. T. McCormack, Kentucky, and carried:

Your reference committee commends the new plan by which local physicians are requested to offer a program on Monday. This plan is especially appropriate in view of the tradition which bars local physicians from reading papers in the section program. It does feel, however, that every effort should be made to select subjects of interest to the general practitioners.

Your reference committee endorses the new "panel" or round table programs on Tuesday and believes that they will continue to prove interesting and informative.

The reference committee feels that the emphasis placed on symposiums in section meetings and on joint symposiums presented by two sections on this year's scientific program is worthy of perpetuation.

The committee congratulates the Council on Scientific Assembly on maintaining the high standards of the Association in this year's program.

Respectfully submitted. GEORGE GRAY WARD, Chairman.

Presentation of Minutes

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. George W. Kosmak, New York, and carried, the House dispensed with the reading of the minutes.

Report of Reference Committee on Medical Education

Dr. Harvey B. Stone, Chairman, presented a report, which was amended to read as follows:

1. Your Reference Committee recommends the adoption of the Resolution Expressing Appreciation of Staff at Headquarters, presented by Dr. E. H. Skinner, Section on Radiology.

2. Your Reference Committee approves and recommends the adoption of the Report of the Council on Medical Education and Hospitals as printed in the Handbook and as contained in the Supplementary Report with the following notations and exceptions:

In paragraph 13 of the printed report, the Council on Medical Education and Hospitals expresses the opinion that the attention of the constituent state societies of this Association should be called to the great importance of controlling the direction of programs of postgraduate education. Your Reference Committee herewith recommends that the House of Delegates empower the Council on Medical Education and Hospitals to carry out this purpose.

In paragraph 14, the Council on Medical Education and Hospitals recommends that it be authorized to send three representatives to act on the Advisory Council on Medical Education, Licensure and Hospitals. Your Reference Committee disapproves of this suggestion and recommends as a substitute the following:

The Council on Medical Education and Hospitals of the American Medical Association is always willing to cooperate with other organizations in those matters with which the Council is concerned. Accordingly, it will be glad to have problems and recommendations presented to it for consideration, or to meet with other organizations in pursuance of the functions of the Council.

In paragraph 4 of its Supplementary Report, the Council on Medical Education and Hospitals requests permission to explore the possibility of cooperative relations with other organizations concerned in problems of graduate medical education. Your reference committee approves of this request and herewith recommends that the House of Delegates grant such permission.

In paragraph 7 of subheading *III* of the statement concerning "Essentials of a Registered Hospital," the Report of the Council enters into considerable detail concerning staff meetings. In the judgment of your committee it would be wiser to strike out this whole paragraph and substitute for it the following paragraph:

Staff meetings should be held for the review of the work of the hospital, the discussion of results, the reports of autopsy and pathologic studies, the presentation of papers and such other matters as concern the professional work of the hospital. Your reference committee herewith recommends this substitution.

Respectfully submitted. HARVEY B. STONE, Chairman.

On motions of Dr. Stone, duly seconded and carried, the report was adopted as amended.

Report of Reference Committee on Reports of Officers

Dr. Floyd S. Winslow, Chairman, presented the following report:

1. Address of the Speaker: Believing that the present and the future may be benefited by a study of the past, your Speaker has reviewed preceding records of the House of Delegates and in this commendable self-imposed task he found considerable good.

He notes and calls our attention to the complexity of representation that unites to give this House of Delegates a true democratic composition. This makes it possible to handle issues of vital importance, issues that are vital not only to the medical profession but to the people as a whole.

Your reference committee believes that the latter point might well be more widely publicized.

The Speaker has very wisely noted the lack of errors and reversal of actions in the past as due to two causes: 1. Our Principles of Medical Ethics, which has given us a philosophy. 2. Faith—a faith that has augmented sound progress and opposed gain at the price of freedom—a faith in coordinated effort on the sound principle of checks and balances working to a common purpose—a faith in one another in a world lacking in faith—and a faith that gives hope in believing that the time may be soon when our loyalty to mankind may again be appreciated by the public.

Your reference committee heartily approves the expression of these ideals so clearly and timely expressed by our Speaker.

2. Address of the President: Your reference committee has given careful consideration to the excellent material contained in the presidential address of Dr. Abell. The evidence of his untiring efforts and the breadth of his vision attest his zeal and constitute a perpetual testimonial to his leadership and high purpose in the profession.

Your reference committee considers as especially noteworthy his strict observance of the principles and policies adopted by this House of Delegates. His suggestion for improving medical care by utilizing existing vacant hospital beds is a step in the right direction and should be adopted and followed.

Your reference committee recognizes the importance of expansion of public health, maternal and child welfare services along the line which he recommended; however, it is well to note his unqualified disapproval of recommendation 4 of the National Health Program.

His reference to the methods used by the government for the purpose of arousing strong sentiment against the American Medical Association shows to what ends a bureaucratic system will resort. The temperate language in this reference is no less a tribute to his forbearance than it is an indictment of those who would see justice trampled under foot.

3. Address of President-Elect: Attention was drawn by the President-Elect to the threats to the science of medicine by social and governmental agencies by creating the impression that there is a near breakdown in medicine. Your reference committee feels that cognizance should be given to such unfounded threats.

His reference to the increasing numbers of medical organizations meets with our approval and deserves consideration by all members of the medical profession. We need stronger union and greater efforts in the solution of our problems. Multiplicity of medical organizations, unless there is definite need for such, only dissipates our strength. Officers and members should refrain from expressing opinions not approved by the American Medical Association, unless they make it clear that it is their personal opinion and not the policy of the organization. Much of the misunderstanding in the bodies of organized medicine is caused by statements of individuals who are believed by the public to speak authoritatively but who, in fact, speak only for themselves.

The President-Elect's reference to the evils concerning the medical profession at the beginning of this century is noted with interest. Those evils were the existence of the proprietary medical schools, commercialized medical directories and proprietary medicines.

Fine leadership contributed toward the correction of these paramount evils. Such leadership can now be depended on to effect a satisfactory adjustment of the present day problems. His reference to the high type of medical journals published by the American Medical Association as compared to those published by some private companies is noteworthy. The contrast is obvious.

The President-Elect refers to the high standard and fearless policy of the Editorial Department of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Such policies merit the continued confidence of the House of Delegates and reflect the ideals of the Editor.

4. Report of the Judicial Council: 1. Ethics of Various Plans of Reducing Sickness Cost: It is obvious that any plan for reducing sickness cost to the low-income population by periodic prepayment should be ethically solved. To this end your reference committee recommends that the Judicial Council be consulted in those instances in which any question of ethics is involved under the plan for consideration.

2. Teaching in Schools of Chiropody or Podiatry: Your reference committee approves the position taken by the Judicial Council with regard to teaching of chiropody or podiatry and recommends that the House of Delegates approve such teaching, provided the schools in which it is conducted are connected with approved medical colleges which require recognized standards of preliminary education. Under such conditions the curriculum is supervised by the state department of education, and graduates of such schools are licensed to practice by examination.

3. Diagnostic Clinics: Your reference committee recognizes the difficulty arising from the effort to define Diagnostic Clinic and commends the conservatism surrounding such an effort. It agrees with the conclusions of the Judicial Council that:

A. A diagnostic clinic is an organization of physicians whose sole work in the clinic is to make or supervise diagnostic examinations of patients referred to the clinic by doctors of medicine, or to collaborate in general diagnostic surveys.

B. The reports of the diagnostic clinic on examinations and tests are made only to the referring physician unless he requests that the case and the recommendations for treatment be discussed with the patient as part of a professional consultation at which the relationship of the results of the diagnostic studies to the general condition of the patient is open for discussion. In such case, discussion is only by a member of the staff.

C. The staff of the diagnostic clinic should include representatives from all the specialties that are of recognized diagnostic usefulness. Every clinical examination, laboratory test or x-ray procedure is made by a physician who specializes in that field or under his supervision. The clinic must be equipped to allow the various specialists to exercise fully their abilities.

D. The control of the clinic must be vested in one or more members of the professional staff. Any profits are to be apportioned only to the members of the staff actually engaged in the work of the clinic. There must be no dividends, bonuses or salaries paid any individual except for services rendered.

E. The clinic must be governed in its activities by the same ethical principles as apply to an individual member of the American Medical Association.

Respectfully submitted.

FLOYD S. WINSLOW, Chairman.
WILLIAM H. MYERS.
JAMES Q. GRAVES.
ELBRIDGE J. BEST.
FORREST J. PINKERTON.

The first three sections of the report of the reference committee dealing with the addresses of the Speaker, President and President-Elect were adopted on motions of Dr. Winslow, duly seconded and carried.

Dr. Winslow moved the adoption of the fourth section of the report dealing with the Report of the Judicial Council, and the motion was seconded by Dr. J. Q. Myers, North Carolina. After discussion, Dr. Winslow moved that the fourth section of the report be adopted with the exception of that part which refers to podiatry, and the motion was seconded by Dr. John Z. Brown Sr., Utah, and adopted after further discussion.

Report of Reference Committee on Medical Education

Dr. Harvey B. Stone, Chairman, presented the following resolution as a substitute for the Resolution Limiting Directorship of Approved Clinical Laboratory to Licensed Physician, which was adopted on motion of Dr. Stone, duly seconded and carried:

WHEREAS, Years ago the examinations made by clinical laboratories were largely factual in nature and, as a consequence, a portion of the work was done by chemists and technicians not having medical degrees or being licensed to practice medicine, and

WHEREAS, The developments in laboratory medicine, particularly in the last one or two decades, have been such as to require clinical medical knowledge for the safe performance of many of the newer diagnostic procedures undertaken; and

WHEREAS, Specimens are obtained by surgical means from the spinal canal, veins and organs of the body and dyes and other drugs are injected for the purpose of various functional tests, all definitely requiring clinical medical experience and judgment for their performance and interpretation if the safety of the patient is to be guarded; therefore, be it

Resolved, That the American Medical Association specifically recognizes the practice of clinical pathology as a specialty of medicine and believes that those persons who practice it and who act as directors of clinical laboratories must be graduates of recognized medical schools and licensed to practice medicine in their respective states; and further be it

Resolved, That owing to the nature of the subject, the American Medical Association recognizes that it is necessary for these persons to complete at least three years of adequate training in clinical pathology, in addition to the training which they have received in regular courses in medical schools, before assuming the directorship of clinical laboratories.

Report of Committee on Legislative Activities

Dr. E. H. Cary, Chairman, presented the following report of the Committee on Legislative Activities, which was referred to the Reference Committee on Legislation and Public Relations:

Mr. Speaker and the Members of the House of Delegates:

Since the last session the members of the Committee on Legislative Activities, individually and collectively, have been drawn into many conferences concerning legislation affecting the interest of the members of the medical profession in the United States.

The committee calls your attention to certain phases of legislation affecting the veterans and medical relief on which it has always reported to the House. In addition it wishes to call your attention to some immediate problems which will require the active service of this committee in cooperation with other members of our organization. It is our hope that the House will make clear to the members of the committee its position on any controversial issue which may come before the Congress.

VETERANS' ADMINISTRATION

A report submitted to the Congress on Jan. 30, 1939, shows that, of the 50,670 veterans under treatment at the end of last year, 47,285 were in facilities controlled by the Veterans' Administration, 2,512 in other government hospitals and 873 in state or civil institutions. Over 63 per cent of these veterans in all hospitals are receiving treatment in the facilities in the state of their reported home addresses. Since March 3, 1919, when the acquisition of the government hospitals was first authorized for the treatment of veterans of the World War, there have been 1,863,289 admissions of veterans of the United States to hospitals, of which 152,966 were made during the last year. This load has been increasing since 1919.

The committee finds that on June 30, 1938, there were in Veterans' Administration facilities 51,991 hospital beds, apportioned to the different classes of patients as follows: neuropsychiatric, 28,119; tuberculosis, 5,121; general, 11,662; general homes, 7,089. During the fiscal year 1939 it is proposed to add 3,453 new beds, as follows: neuropsychiatric, 1,334; tuberculosis, 155; general, 1,012; general homes, 952. During the fiscal year 1940 it is proposed to add 6,731 new beds, as follows: neuropsychiatric, 3,686; tuberculosis, none; general, 2,653; general homes, 392. If the proposed plans are carried out there will be available, as of June 30, 1940, a total of 62,175 beds in veterans' hospitals, as follows: neuropsychiatric, 33,139; tuberculosis, 5,276; general, 15,327; general homes, 8,433. The present hospital building program of the Veterans' Administration is being carried out under an appropriation of $4,500,000 made available directly by the Seventy-Fifth Congress, but this is being supplemented by a sum three times as large, $13,268,200, donated by the Public Works Administration.

The Administrator of Veterans' Affairs contemplates as an ultimate goal 100,000 beds in veterans' hospitals presumably for all classes—one bed for every forty veterans throughout the United States. He estimates that the peak load of hospitalization will be reached in 1949 or 1950. What is to become of these hospital facilities as that load declines is not clear.

In addition to the foregoing hospital bills, H. R. 6041, introduced by Representative Hendricks, Florida, proposes to authorize the appropriation of $1,750,000 to construct a 500 bed capacity veterans' hospital on or near the central east coast of Florida, for the accommodation of general medical and surgical disabilities. The other bill, S. 2257, introduced by Senator Gurney, South Dakota, proposes to authorize the appropriation of $1,000,000 to construct an adequate building or buildings to be used as a veterans' hospital and diagnostic center in the first congressional district of South Dakota. The bill does not indicate what type of hospital it proposes to construct.

It would seem that the Veterans' Administration will continue to build hospitals up to the point of the 100,000 beds or more if money can be developed as it has been the last few years.

MEDICAL RELIEF THROUGH FARM SECURITY ADMINISTRATION

The Farm Security Administration claims that it found it necessary to help provide such medical care in the course of its efforts to rehabilitate more than 700,000 low income or destitute farm families because good health is a necessary part of a family's economic rehabilitation and says that quite aside from any humanitarian purpose, it has, as a lending agency, found that a family in good health is a better credit risk than a family in bad health.

The medical director of the Farm Security Administration reports that it has, through the cooperation of state medical associations, developed plans under which families other than the low income farm families in twenty-three states are being helped to obtain medical care at a cost which they can afford. In general, these plans are simple. They are based on the borrower's ability to pay for medical services, as determined by his farm plan, on free choice of physician and on the setting aside of funds, in the hands of a trustee, at the beginning of the operating period. The amount paid for participation varies in different localities. The usual payment is between $15 and $30 a year for each family. When necessary, the Farm Security Administration will increase the size of its loan to enable a borrower family to participate. The details vary, but a part of the pooled funds held by the trustee is allocated at the beginning of each period for hospitalization and emergency needs including surgical care. The remaining fund is then divided into equal monthly allotments for the period covered.

County plans for medical care are in operation in fifty-six of the seventy-five counties in Arkansas, twelve counties in Missouri, forty in Mississippi, twelve in Texas, twenty-six in Alabama, eighty-five in Georgia, seven in Ohio, five in Tennessee, two in Indiana, seven in Oklahoma, three in Iowa, four in New Mexico, three in Virginia, six in North Carolina, twelve in South Carolina, one in Montana, two in Idaho, fifteen in Louisiana, one in New Jersey and four in Florida, and plans have been made in some other states.

The committee would like to call your attention to a mimeographed report under the title "Medical Care Plans for Low Income Farm Families" issued by the Farm Security Administration April 10, 1939. This report gives a great deal of additional information, as well as a financial report with the breakdown of a typical group, showing that the average family pays approximately $27 a year and just how this money is expended. With respect to North Dakota and South Dakota, which states have benefited most through the Farm Security Administration, it is stated that the funds are distributed as follows: for physicians, 51 per cent; for hospitalization, 37 per cent; for dentists, 8 per cent, and for drugs and medical supplies, 4 per cent.

At the end of each month the bills are submitted to the state office of the North Dakota Farmers' Mutual Aid Corporation

at Bismarck or to the South Dakota Farmers' Aid Corporation at Huron, and they are then reviewed and totaled. If the total amount of these bills is less than the amount set aside for that period, all bills are paid in full; if it is in excess of the amount set aside, each bill is cut proportionately.

Every one is familiar with the publicity which has appeared in some of the national magazines about the Farm Security Administration and knows that it has been stated that this service is "a rehearsal for state medicine."

In a recent letter from the director, Dr. Williams, the following statement is made: "Except in the two Dakotas and in California, the plan is developed on the county as a unit. In some states we have a few larger units consisting of several counties. The problem in the two Dakotas, as you know, is really one of relief. There are something like 18,000 families in each state who because of drought and crop failure (grasshoppers) are receiving grants from the Farm Security Administration. Such a large number of families makes it administratively desirable to handle the plan on a statewide basis."

Nothing has come to the attention of the committee that discloses the methods employed in determining the economic status of persons seeking the benefits of cheap medical service or the standard by which the administration determines whether such benefits shall be granted. Information is available from physicians in North Dakota and South Dakota to the effect that the reported arrangements of the Farm Security Administration are not working well and that funds have been exhausted in many places, thus shifting the load of medical care for the clients back to the medical profession. If any member of the House of Delegates has any additional information that this service is being handled in a manner detrimental to the public welfare, the committee would like to be advised.

Recently the President has submitted to Congress his plan No. 1 for government reorganization. The interest of the medical profession in this proposed reorganization centers in the proposal to create a Federal Security Agency in which will be grouped the United States Employment Service, the office of education, the United States Public Health Service, the National Youth Administration, the Social Security Board and the Civilian Conservation Corps. This plan was submitted pursuant to the authority granted the President in a law approved April 3, 1939, and designated as the "Reorganization Act of 1939." This act, as you may know, provides that the President may submit plans to Congress proposing to (1) group, coordinate and consolidate executive agencies of the government, as nearly as may be, according to major purposes, and (2) reduce the number of agencies by consolidating those having similar functions under a single head, and abolish such agencies or such functions thereof as may be necessary for the efficient conduct of the government.

Members of the Committee on Legislative Activities appeared before a Senate committee last year and conveyed to them the suggestion of the House of Delegates that public health and matters related to medical affairs be placed in the hands of a new cabinet officer, preferably a physician. They were informed that the President was opposed to this idea and that it was unlikely that a new cabinet position would be created.

On January 23 the President transmitted the Interdepartmental Committee report to the Congress, with the recommendation that it be given careful study.

Senator Wagner, on February 28, introduced into the Senate a so-called National Health Bill (S. 1620) and since that time contact has frequently been made with the chairman of the Senate Committee on Education and Labor, to which it was referred. The Association was invited to have representatives appear before the Senate Committee early in May but requested permission to submit simply a brief at that time and to send its representatives after this session of the Association. This request was granted. Therefore, the House of Delegates has an opportunity to consider the Wagner bill. The brief, which in a general way stated the position of organized medicine, was presented on May 5 by Dr. Arthur W. Booth, Chairman of the Board of Trustees, who was subjected to many questions regarding the Wagner bill, and the Committee on Legislative Activities with other members of the association has an opportunity to appear before the Committee on Education and Labor on May 25 to present the views of the medical profession, based on the action of this House.

It is fair to say in this connection that a program was outlined by the Committee on Legislative Activities in cooperation with the Board of Trustees, and that that program, in which the Interdepartmental Committee report was broken down, together with the previous expression of the House of Delegates on each of the subjects, was sent to various gentlemen who are working with the Committee on Legislative Activities.

The committee gladly cooperated with the Board of Trustees and other members of this organization in advocating the survey which was recently made in the 747 counties of the various states covering some 40 million people, and believes that it is a most important contribution. For the purpose, an appropriation was made by the Board of Trustees.

For several years this committee has taken a sympathetic interest in the medical problems of the farm population as expressed by the American Farm Bureau Federation. This federation has under consideration the formation of a mutual assistance plan which would incorporate the principle of cash indemnity to its members, a principle which this House approved at the special session in Chicago in September 1938. The intention of this group to consider the use of principles which are consistent with the actions and policies of the Association deserves our commendation. It is to be hoped that state and county medical societies will be sympathetic to the efforts of this group to solve their own medical problems.

Respectfully submitted.

E. H. CARY, Chairman.
F. S. CROCKETT.
R. L. SENSENICH.
J. H. J. UPHAM.
C. B. WRIGHT.

Resolutions on Opposition to the Wagner Bill

Dr. E. H. Cary, Texas, presented the following resolutions, which had been unanimously adopted by the house of delegates of the State Medical Association of Texas, and which were referred to the Reference Committee on Consideration of the Wagner National Health Bill:

WHEREAS, There has been an effort for some years on the part of certain individuals to bring about in this country a system of practice of medicine in which the relation of the patient and his family doctor as it now exists will undoubtedly be destroyed; and

WHEREAS, The Interdepartmental Committee study and report was based on a national health survey made by Works Progress Administration workers under the surveillance of the United States Public Health Service, which survey led to the statement that there were forty million people in the United States without adequate medical care; and

WHEREAS, There followed a survey directed by the Board of Trustees of the American Medical Association through its constituted state associations, in which survey the medical, dental and nursing professions, together with the social and welfare workers, hospitals, schools, health departments, industry, labor and other organizations, have shown that of the forty million people in the 747 counties in the United States covered by the American Medical Association study no considerable number are unable to secure medical service if and when they need it; and

WHEREAS, In a survey in Texas which has been a part of the aforementioned survey by the American Medical Association, the facts developed have been essentially the same; and

WHEREAS, The Wagner bill has been predicated on the national survey of the Interdepartmental Committee; and

WHEREAS, The medical profession has always favored the extension of preventive medicine as part of the work of the United States Public Health Service operating through the state health agencies; and

WHEREAS, The medical profession has traditionally taken care of the indigent sick and would welcome any economic change in the country looking to the better care of the indigent sick; and

WHEREAS, There is an average of 31.1 per cent of the hospital beds unoccupied and the medical profession would be deeply interested in some effort to relieve this economic waste of the facilities already provided for the care of the sick and would gladly support a measure which would provide a hospital in any section of the country where an actual need exists and where there is proper professional personnel to staff it; and

WHEREAS, The Wagner bill No. S. 1620 obviously leads by indirection to compulsory health insurance, to which the medical profession is bitterly opposed; therefore be it

Resolved, That our senators and representatives in Congress be requested to oppose the Wagner bill; and be it further

Resolved, That the medical profession of Texas stands ready at any time to further any reasonable plan, through the proper agencies existing in Texas, to solve such problems as are considered in the Wagner bill.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. John H. Fitzgibbon, Chairman, presented the following report, which was adopted section by section and as a whole on motions of Dr. Fitzgibbon, duly seconded and carried:

REPORT OF THE SECRETARY

Your reference committee has read with satisfaction the report of the Secretary, which indicates that an increasing number of physicians are alining themselves with organized medicine. This growth, bringing the membership to more than 113,000, the highest number ever recorded, is eloquent and convincing testimony in refutation of the claims made in some quarters that there is dissatisfaction in the ranks of the profession.

Your reference committee notes with approval the comment of our Secretary that, on returning to their respective jurisdictions, members of this House of Delegates have in certain instances promptly prepared and published informative reports and résumés of the actions of this body. Your reference committee believes that this practice should be more widely adopted. In view of the widespread interest of both professional and lay groups in the actions of the House of Delegates, our members, whose training best qualifies them to do so, should be encouraged to disseminate the desired information in regard to our activities.

Your reference committee believes that it voices the sentiment of this House of Delegates in expressing appreciation to our Secretary for the untiring efforts manifested by him over a long period and particularly during the past year with its unusual problems.

REPORT OF BOARD OF TRUSTEES

Your reference committee approves in general the interesting and comprehensive report of the Board of Trustees. The report contains so much of interest and importance that the lack of time for adequate comment is regretted. It desires, however, to comment on some of the more important features of the report.

Your reference committee notes with interest and concern that as the result of increased and unusual activities the total expenditures of the Association for 1938 exceeded by more than $11,000 the annual income. It is hoped that there will be lessened emergency expenditures and that the increase in the Fellowship dues and subscriptions will provide sufficient future revenue to meet increased cost of operation and for the continuation of the normal activities of the Association.

The history of THE JOURNAL shows continued advancement and extension in fields of scientific and economic interest. The addition of the Student Section and the development of the Organization Section have undoubtedly increased the value of THE JOURNAL and distinguished it from all similar publications. The reference committee would like to suggest that the Organization Section include items of general economic interest and that the material in this section be edited so as to make it easy to read.

Your reference committee suggests that, owing to general economic conditions, the editorial policies of the special journals be guided to some extent by economic considerations.

Your reference committee approves the action of the Board of Trustees in meeting with representatives of recognized hospital associations and other national organizations and urges continued cooperation with these groups. It recommends approval by the House of Delegates of such action by the Board of Trustees.

In regard to the communications from the National Medical Association, Inc., your reference committee feels that the points raised by that association relative to listing its members in the American Medical Directory should be carefully considered by the Board of Trustees. It is noted that the Board feels that a method for listing Negro physicians in a manner not objectionable to them may be worked out.

Your reference committee commends the creation of the Division of Drugs, Foods and Physical Therapy and feels that such coordination will expedite the activities of the various councils included.

Your reference committee recommends that the House of Delegates approve the action of the Council on Physical Therapy regarding the standardization of tests for hearing for the estimation of compensation, as well as for other purposes. The program of work outlined by this Council is being started at this meeting of the American Medical Association.

Your reference committee notes with approval the vigorous manner in which the Association's newest Council, that on Industrial Health, has approached the objectives included in its field.

Your reference committee commends the efforts of the Bureau of Health Education to inform the public in matters of health, and particularly its increased activity in radio broadcasting and the appearance of its personnel before lay groups.

The work of the Bureau of Medical Economics deserves careful study by the House of Delegates as well as by all other members of the Association. Among the major activities should be mentioned the national survey of the need and supply of medical care. With the aid and cooperation of physicians and medical organizations throughout the country, the Bureau has assembled a great volume of data of value in meeting the economic problems of medicine. This material will be published in a special volume which will merit careful study.

The Bureau is commended for its continued study of medical service plans, group hospitalization and other economic problems and for the reports it has prepared on these subjects.

Your reference committee wishes to congratulate the Bureau of Exhibits on the high quality and educational value of the scientific exhibits at this and the San Francisco session.

Your reference committee approves the supplemental report of the Board of Trustees concerning the Army Medical Library.

The Bureau of Legal Medicine and Legislation is commended for its continued efforts in behalf of the profession during the past year.

In concluding this report, your committee wishes to say that it feels that it has the sympathetic understanding of this House in recording its inability to present in the time available even a brief summary of the condensed activities of the Board and Secretary covering some 100 pages in the Handbook. It is acutely aware, as it knows you are, of the herculean task which their offices impose. Your thoughtful rereading of these illuminating pages is urgently recommended.

It is not of their recorded activities but, rather, of the personalities of the men composing these agencies of our Association that we desire now to speak. Inspired by no thought of reward save the hope that their efforts throughout the interval between our annual sessions may preserve for the people of this country the American system of medical care purchased through the enlightened leadership and sacrifices of our forebears, they struggle without complaint with the ever increasing problems which vex us. Through these labors, supported by the rank and file of our profession, ethical and humanitarian principles so dear to us are to be preserved.

Your reference committee records these sentiments in the hope that full and appreciative recognition of the vital functions performed by the Secretary and the Board may serve to warm the deeper recesses of their hearts and help to sustain them in the arduous days that lie before us.

Respectfully submitted.

JOHN H. FITZGIBBON, Chairman.
J. NEWTON HUNSBERGER.
GRANT C. MADILL.
CHARLES W. ROBERTS.
W. F. BRAASCH.

Report of Reference Committee on Miscellaneous Business

Dr. H. C. Macatee, Chairman, presented the following report, which was adopted section by section and as a whole on motions of Dr. Macatee, duly seconded and carried after discussion by Drs. Arthur J. Bedell, Section on Ophthalmology, and Dr. Macatee:

Resolution on Testing of School Children for Early Detection of Defective Vision and Hearing: Your reference committee recommends that this resolution, presented by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, be endorsed and that all state medical societies be encouraged to

originate programs through county societies to carry out the purposes of the resolution or to foster such programs as already exist.

Communication from the Department of Christian Social Relations of the Episcopal Diocese of Western Michigan: This communication seemed to your reference committee to be germane to the work of the Committee on Consideration of the Wagner National Health Bill (S. 1620), to which committee it was transmitted. However, the Committee on Miscellaneous Business recommends that, on completion of consideration of the Wagner bill by this House, the sender of this and similar communications be informed of the action taken with an expression of the hope that the American Medical Association may count on their continued support.

Respectfully submitted.

HENRY C. MACATEE, Chairman.
BEN R. MCCLELLAN.
FRED MOORE.
WILLIAM WESTON.
E. S. HAMILTON.

Report of Reference Committee on Legislation and Public Relations

Dr. Holman Taylor, Chairman, presented the report of the Reference Committee on Legislation and Public Relations, which as amended reads as follows:

1. Report of the Committee to Study Problems of Motor Vehicle Accidents: This is a report of progress. It is, however, rather complete and comprehensive. It covers problems of physical and mental defects and of alcoholic intoxication. The defects are permanent deficiencies, transitory deficiencies and incidental deficiencies, all of which, it is pointed out, may be either compensated for or relieved. The most disturbing element in automobile driving, it seems, is alcoholic intoxication. This phase of the problem is, in our opinion, handled quite adequately. The application of chemical tests is made, and metes and bounds for medicolegal interpretation are set up. Your reference committee considers the standards thus raised to be fair and just and protective of the interests of both the individual and the authorities. It recommends the adoption of the report.

2. Resolution on Medical Care to the Indigent: Your reference committee finds itself in thorough sympathy with the resolution on Medical Care to the Indigent presented by Dr. Walter B. Martin, Virginia. However, it appears that this House of Delegates has already adopted, in principle and in fact, the recommendations of the resolution. It does not appear necessary, or even advisable, that they be readopted at this time on the recommendation of this committee. The matters concerned in the resolution are now being considered by the Reference Committee on Consideration of the Wagner National Health Bill. Your committee has taken the liberty of furnishing that committee with a copy of the resolution and recommends that the entire matter be so referred.

3. Medical Patents: The report on medical patents is a supplementary report of the Board of Trustees on a matter referred to it by this House. It is merely a discussion of the situation and carries no recommendations. It appears to your reference committee, however, that something should be done about it.

Since the beginning of medical ethics it has been held that it is not proper for a physician to receive financial rewards from any patent covering any agency useful in either prevention or cure of disease, the idea being, of course, that there should be no restrictions on the use of such agencies so that all may alike be benefited. Of recent years, however, the situation has changed remarkably. New problems of great moment have arisen. The honored traditions of the medical profession are in grave danger because of these changes. It appears on the one hand that discoveries in medicine should be protected through patents so that purity may be preserved and the public thereby protected, on the other hand that this effort instead of helping is likely to hamper. Further progress in any particular development which is under patent can be made only through the consent of the holder of the patent. It does not appear that the physician making a discovery which is patented for whatsoever reason now profits materially therefrom.

It seems to your reference committee desirable that some change in our Principles of Medical Ethics should be made. If, as seems to be the case at present, the individual physician, or other individuals, may not profit from any discoveries made, and we do not see how arrangements to change that can be effected, it would be better either that patents be not taken out or that, in those rare instances in which patents are necessary, they be dedicated to the public. Your reference committee recommends that the matter be referred to the Judicial Council of the American Medical Association with the request that it rewrite accordingly the section of the Principles of Medical Ethics referring to patents, and that its report be returned to the House of Delegates for action. Your reference committee recommends further that the proper officials of the American Medical Association be requested to call this matter to the attention of other organizations having to do with health problems, and particularly to the Council on Pharmacy and Chemistry and the Council on Foods of the Association and the laboratories of the United States Public Health Service.

4. Resolution on Granting a Seat in the House of Delegates to a Woman Delegate: This resolution appeals to your reference committee as being one of the most far-reaching resolutions introduced at this session. A division of the medical profession along the lines of sex for any professional purpose appears to be unwise. Beyond any doubt, a policy along the lines of the resolution would make the Association liable to similar demands from a variety of groups. Indeed, this has already happened. It is likewise certain that to grant our women physicians the representation sought in this resolution would be to establish multiple representation. Our women physicians are now entitled to the representation they seek through regular channels. They have the same opportunities for selection that other members enjoy. To permit the selection of members of this House of Delegates by extramural organizations, organizations over which the House has no control, would be to break the rationale of our plan of organization. Certainly it would be necessary, in order to grant the petition embodied in this resolution, to amend our organic law. Your reference committee recommends that the resolution be not adopted.

5. Resolution Urging That Membership in the American Medical Association Be Not Denied Solely on Basis of Race, Color or Creed: Your reference committee has given this resolution careful and sympathetic consideration. While the resolution does not provide for arbitrary action or any force to the end sought, it does set up a policy. In doing that, the resolution implies that the county medical society should not, in effect, have the right of selection of its own members, a fundamental principle in our organization. Readjustment along the lines of the resolution are rapidly taking place in those states most vitally interested. Your reference committee recommends that the resolution be not passed.

Respectfully submitted.

HOLMAN TAYLOR, Chairman.
L. G. CHRISTIAN.
KARL S. J. HOHLEN.
THOMAS P. FARMER.
G. HENRY MUNDT.

The report of the reference committee was adopted, as amended, section by section and as a whole on motions of Dr. Taylor, duly seconded and carried, after discussion.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. Charles E. Mongan, Chairman, presented the following report:

1. Resolutions on Rearrangement and Rewording of the Principles of Medical Ethics: Your reference committee feels that any proposed change in the Principles of Medical Ethics of the American Medical Association is a matter for serious consideration and that such a study as the resolutions demand should be done by a body of the American Medical Association which has to do with the administration of the Principles of Medical Ethics in the last analysis.

Your reference committee therefore recommends that these resolutions offered by the California delegation be referred to the Judicial Council for study and that the Judicial Council

report to the House of Delegates its conclusions at the session of 1940.

2. Resolutions on Exhibition of Medical or Surgical Procedure to Lay Groups: Your reference committee is of the opinion that the evil complained of can be best settled by local supervision through state or county societies. Such procedure will not necessitate any changes in the Principles of Medical Ethics of the American Medical Association as at present enunciated.

Therefore your committee recommends that such a procedure be followed by the state and county medical societies.

Respectfully submitted.

CHARLES E. MONGAN, Chairman.
T. K. GRUBER.
EDGAR A. HINES
FELIX P. MILLER.
E. G. WOOD.

The report of the reference committee was adopted section by section and as a whole on motions of Dr. Mongan, duly seconded and carried.

Report of Reference Committee on Rules and Order of Business

Dr. John H. O'Shea, Chairman, recommended that the Executive Session of the House of Delegates convene at 1:30 p. m. Wednesday, May 17, instead of at 1:15 p. m. Tuesday, May 16. The motion was seconded by Dr. John Q. Myers, North Carolina, and carried.

Expression of Appreciation

Dr. George W. Kosmak, New York, moved that the House by a rising vote express its appreciation to the various reference committees for their activities. The motion was seconded by several delegates and carried unanimously.

Dr. Arthur J. Bedell, Section on Ophthalmology, moved that when the House recesses today it do so until tomorrow at 1:30 p. m., and the motion was seconded by Dr. A. A. Herold, Louisiana, and carried.

NEW BUSINESS

Resolutions Proposing Amendments to the By-Laws

Dr. J. E. Paullin, Section on Practice of Medicine, introduced the following resolutions, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws and to the Reference Committee on Medical Education:

WHEREAS, The establishment and maintenance of suitable standards in the field of medical education is becoming of increasing importance; and

WHEREAS, The gradual development of the hospital as a center for the training of interns and residents and for graduate medical education of the physician has raised many new problems; and

WHEREAS, The creation of examining boards in the medical specialties and the establishment of many organizations concerned with the qualification of specialists have thrown a greatly increased burden and responsibility on the Council on Medical Education and Hospitals; and

WHEREAS, It should be apparent that the leadership in correlating the various interests concerned with these problems must rest on the American Medical Association as being the one and only organization embracing in its membership representatives of all these interests and activities; therefore be it

Resolved, That the By-Laws of the American Medical Association be amended as follows:

1. Amend chapter VII, section 3, by eliminating "(b) Council on Medical Education and Hospitals" so that that section when amended shall read as follows:

SEC. 3. STANDING COMMITTEES.—Standing committees shall be the following:

(a) Judicial Council.
(b) Council on Scientific Assembly (as amended, 1923 and 1939).

2. Amend chapter VIII, section 1, by deleting the portion beginning on line 4 "The Council on Medical Education and Hospitals" to the sentence beginning "The Members of the Council on Scientific Assembly," and by inserting the following: The Council on Medical Education and Hospitals shall consist of nine members, each elected for five years, two being elected each year for four consecutive years until the fifth year, when one shall be elected. The members of the Council shall be selected by the Board of Trustees, who shall make their choice on the basis of securing for membership in the Council representation from general medical practice, special medical practice, medical education and graduate medical education. Members of the Council shall be eligible for not more than two consecutive terms. This Council shall prepare each year a report of its work and its recommendations, which shall be submitted to the House of Delegates.

3. Amend chapter IX, section 2, by inserting after the words "medical education" in line 4 the words "including premedical, undergraduate and graduate medical education"; and be it also

Resolved, That the present members of the Council on Medical Education and Hospitals shall be continued as members until the terms for which they were appointed shall have expired and that they shall be considered eligible for reappointment.

Resolution on Prescribing of Radium

Dr. E. S. Hamilton, Illinois, presented the following resolution, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws and to the Judicial Council:

The report of the Special Committee appointed by the President of the Adams County Medical Society (Ill.) to study the present ruling of the American Medical Association relative to the rental of radium is as follows:

WHEREAS, At the San Francisco session last year the House of Delegates of the American Medical Association passed certain resolutions condemning the rental of radium under certain conditions, namely, the prescribing and directing of the use of radium in the case of a patient whom the prescriber has not examined or seen; and

WHEREAS, In consideration of the fact that such a rigid ruling would work a great hardship on thousands of members of the American Medical Association and cause great suffering to thousands of citizens of the United States, especially those who are remotely situated from sources of radium; that many patients would be denied the use of radium if they were compelled to make long trips to a source of radium; that many patients have such great confidence in their physicians that they distinctly prefer that he personally administer such radium treatment; that since the pioneers in radium therapy and probably the greatest advocates of radium were not radiologists but leading gynecologists and dermatologists; that since many specialists are well qualified to make many of the applications of radium, because of their specialized knowledge and surgical technic, as is the average radiologist; that since an experience of over twenty-five years, during which time many thousands of patients have been treated, has shown that many conditions in which radium is commonly used can be satisfactorily treated and with great benefit to the patient by the average physician under proper supervision and without a radiologist personally examining the patient on whom the radium is to be used; that because of the great expense of radium it is not practical for the average physician to own it; that the average physician sees so few cases in which radium is needed in his practice that it is not practical for him to make the large financial outlay to purchase it, and that since it is already considered an ethical procedure for physicians to lease radium for long periods or to own it outright, regardless of their qualifications to use it; therefore be it

Resolved, That it is considered ethical for a member of the American Medical Association personally to describe or write a description of a patient on whom he wishes to consider the use of radium and submit it to an experienced radiologist who likewise is a member of the American Medical Association; that if the condition is one in which radium is frequently used and if the radiologist believes the physician submitting the description can use radium with benefit to the patient, he may, therefore, prepare suitable radium applicators, recommend a technic of application and suggest dosage for the treatment of the case under consideration.

A motion to adopt this resolution with the recommendation that a copy be sent to the Secretary of the Illinois State Medical Society, and that the delegate of the Adams County Medical Society be instructed to present it to the House of Delegates of the Illinois State Medical Society at its next annual session (Rockford) for their approval and with the request that the delegates of the Illinois State Medical Society be requested to present it to the House of Delegates of the American Medical Association at its St. Louis meeting was adopted without dissenting vote.

The Committee on Resolutions recommended the approval of the resolution presented by the Adams County Medical Society and the concurrence in its recommendations.

Adopted by House of Delegates May 4, 1939, Illinois State Medical Society.

Resolutions on Army Medical Library and Museum

Dr. Henry C. Macatee, District of Columbia, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

The following resolutions were adopted by the Medical Society of the District of Columbia at its annual meeting held May 3, 1939:

WHEREAS, The Army Medical Library and Museum are housed in a building entirely inadequate for their present purposes and without possibility of expansion for future growth; and

WHEREAS, The immensely valuable collection of medical literature and of anatomic and pathologic specimens is in constant danger of destruction both from the hazards of fire and from the limited space for their proper preservation; and

WHEREAS, The Army Medical Library and Museum constitute a monumental asset both to the United States government and to the medical profession of the entire country; and

WHEREAS, The Secretary of War was authorized by Act of Congress, approved June 15, 1938, to construct a building to replace the present quarters of the Army Medical Library and Museum but was not enabled by the necessary appropriation to carry out the purpose of the Act; now *therefore be it*

Resolved, That the Medical Society of the District of Columbia respectfully petitions the Congress to provide the necessary funds for a new and adequate building for the Army Medical Library and Museum at as early a date as possible; and

Resolved, That copies of this resolution be forwarded to the President of the United States, to the Secretary of War, to the Director of the Budget, to the Surgeon General of the Army, to the Chairman of the Senate and House committees on military affairs and to the senate and house committees of the District of Columbia; and be it further

Resolved, That the delegates be instructed to present this resolution to the House of Delegates of the American Medical Association at the St. Louis Session and to endeavor to secure the endorsement of its purposes by that House.

These resolutions are presented to this House with the request that they receive your endorsement.

Report of Committee on Medical Care

Dr. W. F. Braasch, Chairman, presented the following report, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

The objectives of the American Medical Association in making this survey were to obtain all available facts about the need and supply of medical care in the United States. Nine special forms were prepared and distributed to individuals and agencies concerned with the care of the sick, including physicians, dentists, hospitals, nurses, pharmacists, health departments, private and governmental welfare and relief agencies, private and public schools, universities and colleges, and industrial, fraternal, mutual benefit, group hospitalization and similar organizations.

Interest in the survey varied greatly in different sections of the country, as well as in adjoining states and counties. Among the barren areas may be mentioned some states in which, apparently because of historic aloofness to innovations, but little cooperation was given. Then, too, several states in which recent poorly conceived surveys had been made, with great expense and doubtful results, were delinquent. One state relied on data gathered in a previous state survey, which, however, did not fit in with the objectives of this survey. Several states were late in getting interested and, as a result, their reports are still being held up. One state made a rapid survey, conducted largely by local health officials, and apparently they did not think the results obtained were worth while since the data were not sent in.

No attempt was made to dictate how this survey was to be conducted. Since circumstances varied widely in different parts of the country, no nationwide plan could be followed.

LOCAL TREATMENTS OF THE SURVEY

It was urged that each county medical society appoint a committee to discuss all the results, and to prepare a report with recommendations for improvement. There were many county medical societies in which this was done. Some of these committees prepared reports in the form of bound volumes of considerable size, including special types of investigation or material from previous local studies. Such county medical societies found that when the survey was used in such a thorough manner it formed a new foundation for local medical programs.

State medical associations were urged to take the county reports, and, after adding an analysis of statewide medical activities, to summarize the situation in the entire state and to offer suggestions for improvements in medical organization. Some state medical associations deserve special mention for the service which they rendered the medical profession of their own state and of the whole country in making this survey. New Jersey may be offered as an outstanding example: its state report forms a large volume which covers every type of medical problem and lays the foundation for further study and for solutions where these are possible. It is noteworthy that, while several states pleaded lack of funds as a reason for not undertaking the thorough analysis, discussion and summary which were urged, New Jersey reports that only $600 was expended in preparing its report. Examples of studies in individual counties and states have already been published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

EXTENT OF COVERAGE

Up to the present time, 502 county medical societies have sent returns from 763 counties in thirty-seven states. The total population of these counties in 1930 was 43,790,068. Every section of the country was covered, and reports were received from every county in several states.

This survey is more nearly representative of both urban and rural populations than any previous study. Using the standard accepted by the United States Bureau of the Census prior to 1930, it is assumed that the urban population is composed of those living in cities of 2,500 population or more and that all others are rural. According to this standard, the urban population included in this survey was 28,694,853 and the rural population 15,095,215. Reports were received from practically every county in eight states. Returns are still being received and the final report will be even more complete in its coverage.

The survey of the American Medical Association was not designed primarily to produce a statistical report but rather to obtain a consensus as to the need and supply of medical care; yet it revealed certain statistics of sufficient accuracy to be worthy of presentation. Replies were received from 20,199 physicians and dentists. Many counties did not separate returns made by physicians from those made by dentists, and in some localities forms were sent only to physicians. The ratio of returns received from physicians and dentists in counties where a separation was made leads to the conclusion that about 17,000 of the 20,000 forms returned were filled out by physicians. These 17,000 physicians report *giving medical service without* charge to 2,611,451 persons. This is a little more than 5 per cent of the population covered by the study. Since the number of those who replied was less than 25 per cent of the physicians in the area covered, we are certainly within safe limits of error *if we assume that double this* amount of gratuitous service was given in all the physicians' offices and patients' homes during *this period.* This would mean that 10 per cent of the population was given this type of free service. This same fraction (about *25 per cent)* of the total number of physicians gave 1,909,713 hours of service in hospitals and clinics in addition to the care of patients at home or in physicians' offices. Any sort of calculation based on these facts demonstrates that the previously used estimate of $1,000,000 a day of *free service by physicians* in the United States is far below the actual figure. These preliminary estimates will be reviewed, if necessary, in the final report. Another and more detailed, and probably more accurate, check of the amount of free services given by physicians will be provided when Forms IF are completed and tabulated.

The cooperation received from sources other than the medical profession was especially gratifying. Hospitals, nurses, health departments, private or governmental welfare and relief agencies, private and public school systems, universities and colleges, industrial, fraternal, mutual benefit, group hospitalization and similar organizations as well as pharmacists filled out 13,933 forms.

WHAT THE REPLIES INDICATE

Next in significance to the comprehensiveness of the sources of information is the unanimity of the replies. If the nurses, hospitals, health departments and relief organizations had differed sharply with the physicians as to the adequacy and accessibility of medical care, there would have been justifiable suspicion of the accuracy of the survey. No such conflict appears in reports from any section of the United States. Whenever physicians report inadequate provision of medical care by relief authorities, this judgment is confirmed by welfare and relief officials. Wherever physicians found difficulty in procuring hospitalization for certain classes, hospital authorities said there were too few beds. When fully 90 per cent of the physicians found that practically every person needing and desiring medical service could obtain it, the hospitals, health departments, nurses and welfare workers confirmed this report. The reason for this unanimity is clear. All were dealing with different phases of the same set of facts and not with theories.

They all saw the same things, and the reports of what they saw were bound to agree if stated honestly and accurately. Such differences as appear were shared by each category of reporters.

The points of general agreement are also significant. There was almost complete unanimity and universality of opinion that medical services provided by governmental agencies were the ones most apt to be insufficient. Governmental provisions for medical care for the indigent are everywhere inadequate, except as supplemented by gratuitous services of physicians. From many states came complaints of overcrowded facilities for the care of the mentally diseased, the feebleminded and the tuberculous. For these categories of patients greater expenditures are recommended. School examinations tend to become perfunctory and are not followed by treatment of the defects discovered. This is most frequently explained as being due to indifference or objections of parents to medical care, although there is occasional criticism of lack of interest on the part of school authorities in following up physical examinations with action. Although information concerning dental services appeared to be incomplete, the dental reports indicate that insufficient dental care was received by school children, the indigent and the low income classes. Comments affirmed that much of this deficiency is due to indifference and lack of education concerning the need of dental care, although economic reasons were frequently given.

To the key question which the survey was primarily designed to answer, as to whether any large section of the population is unable to obtain needed and desired medical care, the answer is so nearly unanimous and universal that it should be considered conclusive. Fully 90 per cent of all the sources consulted reported that they knew of no significant number of persons needing and seeking medical care who were unable to obtain it. Nurses, health departments, relief and welfare workers, school and university authorities, industrial and mutual organizations and pharmacists were all asked how many, if any, persons of whom they had knowledge had been unable to obtain needed medical care. They were then asked to comment on any such unmet need and offer any suggestions as to how it could be met. These suggestions and comments are now being analyzed and compiled, and the results promise to offer a body of helpful criticisms and proposals of value in developing better plans for providing medical care.

The overwhelming majority of opinions from all sources agree that forty thousand and not forty million persons in the United States are denied needed medical service. Reports of inability of individuals to secure service are usually accompanied by suggestions of changes in the local organization of medical care by which the needed service can be supplied, and there are numerous reports of such changes being made as a result of the survey.

When to these direct and specific facts are added the many comments and suggestions by the most competent body of trained observers on medical conditions in the United States, the total is the most comprehensive and accurate survey of the need and supply of medical care ever collected. While a full analysis and discussion of comments must await the completed report, sufficient study has been made to permit some generalities.

Much more than a majority of the comments are to the effect that all those who needed and sought medical care received it. Examples of failure to secure such care when needed were usually explained as being due to local conditions not generally difficult to remove. In addition to the inadequacies already mentioned, numerous observers noted the lack of proper accommodations for chronic illnesses, transients and convalescents. Although general proposals for improvements in the organization of medical service were numerous, they formed but a small percentage of all comments. There were many suggestions that plans of medical societies now under way offered possibility of removing many of the difficulties and that some system of prepayment might be desirable for the low income class. There was only an occasional recommendation for compulsory health insurance. It is apparent from the comments made that the great majority of our profession are favorably inclined to changes which would fulfil the needs of local conditions but are opposed to radical changes in the present system of medical care.

One of the important by-products of this survey is that it established methods of more direct cooperation between the central organization of the American Medical Association and the state and county medical societies. This should be of value in the future in carrying out other health activities of national scope.

A working alliance has been established between various agencies allied in medical care which should be of much benefit in future consideration of medical care.

Because of the ever changing nature of medicine, it would be desirable to continue similar appraisals at intervals in the future. Profiting by past experience and with simplification of methods employed, your committee believes that wide cooperation will be given by members of the profession.

Before closing, it should be said that all those who took part in carrying out this survey deserve great credit, since it involved the sacrifice of much time and effort on their part. Particular praise should be given to Dr. Leland and his associates in the Bureau of Medical Economics for their able supervision of the countless details necessary to the execution of this great project.

Respectfully submitted.

WILLIAM F. BRAASCH, Chairman.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded and carried, the House recessed at 12:30 p. m. to reconvene at 1:30 p. m. on Wednesday, May 17.

(To be continued)

REGISTRATION AT ST. LOUIS

The total registration at the St. Louis session was 7,412. Below are given two summaries—one by sections and one by states:

Registration by Sections

Practice of Medicine	2,534
Surgery, General and Abdominal	1,265
Obstetrics and Gynecology	561
Ophthalmology	376
Laryngology, Otology and Rhinology	258

OFFICIAL NOTES

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 1 p. m. eastern standard time (12 noon central standard time, 11 o'clock mountain time, 10 a. m. Pacific time).

Starting April 30, daylight saving time took effect in Chicago. The program is therefore being broadcast at the same hour Chicago daylight saving time, which means one hour earlier central standard time, two hours earlier mountain time and three hours earlier Pacific time. In communities where daylight saving time is in effect there is no change in the hour of the broadcast.

Owing to network conflicts the Chicago broadcast does not occur at 1 o'clock Wednesday but there is a rebroadcast from a recording over station WENR at 8 o'clock each Monday evening (8 o'clock Chicago daylight saving time, 7 o'clock central standard time). The program broadcast each Monday is identical with the network program of the preceding Wednesday.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

May 31. Checking Up on Health.
June 7. Vacations—Why and How.
June 14. Never Stop Learning.

RADIO BROADCASTS FROM THE ST. LOUIS SESSION

The following radio programs were arranged by the Bureau of Health Education and broadcast in connection with the recent meeting of the American Medical Association at St. Louis:

Network Broadcasts:

NBC, Blue:
Irvin Abell, "American Medicine Today."
CBS:

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. J. Res. 138 has been reported to the Senate with recommendation that it pass, providing that the President's Reorganization Plans No. I and No. II shall take effect on July 1, 1939. Under Reorganization Plan No. I the United States Public Health Service will be transferred from the Treasury Department to the newly created Federal Security Agency and there grouped with the Social Security Board, the United States Employment Service, the Office of Education, the National Youth Administration and the Civilian Conservation Corps. H. J. Res. 180 has passed the House, authorizing the President to invite foreign governments to participate in the seventh International Congress for the Rheumatic Diseases, to be held in New York, Philadelphia and Boston in 1940 under the auspices of the International League Against Rheumatism. H. R. 2987 has passed the House and Senate providing for the compensation of any employee of the United States government who shall furnish blood for transfusion to a member or former member of the military establishment who is a patient in a government hospital.

Bills Introduced.—H. R. 6249, introduced by Representative Reece, Tennessee, provides that any ex-service man shown to have had tuberculosis of a compensable degree shall, under certain conditions, receive not less than $100 a month for the remainder of his life. H. R. 6270, introduced by Representative Myers, Pennsylvania, proposes to amend the Social Security Act so as to extend the old age benefit provisions to certain nurses in respect of their employment outside of religious, charitable and other nonprofit institutions. H. R. 6319, introduced by Representative Schafer, Wisconsin, proposes to authorize outpatient treatment for non-service connected disabilities of a World War veteran if such veteran has a 50 per cent disability or more directly incurred in or aggravated by service in the World War. H. R. 6352, introduced by Representative Keller, Illinois, proposes to authorize the Secretary of the Interior to make inspections and investigations in coal mines to obtain information relating to health and safety conditions, accidents and occupational diseases therein. H. R. 6377, introduced by Representative Mundt, South Dakota, proposes to authorize an appropriation of $1,000,000 to construct a veterans' hospital and diagnostic center in the first congressional district in South Dakota. S. 2304, introduced by Senator Reynolds, North Carolina, provides that all hospital facilities under the control and jurisdiction of the Veterans' Administration shall be available for any insane person who has served in the Regular Army, Navy or Marine Corps of the United States for ninety days or more, not dishonorably discharged, without regard to the cause of such insanity. S. 2442, introduced by Senator Burke, Nebraska, provides that, in the administration of the Veterans' laws, retired enlisted men of the Army, Navy, Marine Corps and Coast Guard who served in any war, suffering from any ailment, disability or disease shall be entitled to hospitalization and domiciliary care in Veterans' Administration facilities, without regard to the nature or origin of such ailment, disability or disease. S. 2353, introduced by Senator Sheppard, Texas, and H. R. 6225, introduced (by request) by Representative May, Kentucky, propose to authorize an appropriation of $375,000 for the construction, rehabilitation and installation at Carlisle Barracks, Pennsylvania, of a medical field-service school, and such utilities and appurtenances thereto as may be necessary.

DISTRICT OF COLUMBIA

Bills Introduced.—S. 2351, introduced (by request) by Senator King, Utah, and H. R. 6266, introduced by Representative Nichols, Oklahoma, provide for the incorporation of certain persons as Group Hospitalization, Inc., the corporation to be authorized (*a*) to enter into contracts with individuals or groups of individuals to provide for hospitalization of such individuals, (*b*) to enter into contracts with hospitals for the care and treatment of such individuals and (*c*) to cooperate, consolidate or contract with groups or organizations interested in promoting and safeguarding the public health.

STATE MEDICAL LEGISLATION

Connecticut

Bills Introduced.—H. 1618 proposes to require all applicants for examination before the State Board of the Healing Arts to be citizens of the United States. As it is necessary for all applicants for licenses to practice any branch of the healing art to pass examinations before the State Board of the Healing

Arts in anatomy, physiology, hygiene, pathology and diagnosis before presenting themselves to their respective professional boards for licensure, the enactment of this bill, in effect, would limit licensure in the healing art to citizens of the United States.

Bill Passed.—House Substitute for House 1485 has passed the house and the senate, proposing so to amend the laws relating to the practice of chiropractic as to require licensed chiropractors to renew their licenses annually with the chiropractic board and to condition renewal on the presentation of satisfactory evidence that the applicants in the preceding year have attended at least one of the two day educational programs as conducted by the Connecticut Chiropractic Association, Inc.

Florida

Bills Passed.—H. 760 has passed the house and the senate, proposing to authorize the Board of County Commissioners of Clay County to levy an additional annual tax not to exceed 1 mill on the dollar of assessed valuation, the proceeds of which is to be used to care for indigent residents of the county who are in need of hospitalization and medical care. H. 762 passed the house, proposing to authorize the organization in counties having a population of not less than 85,000 and not more than 165,000 of corporations to operate nonprofit hospital service plans whereby hospital care may be provided by such corporations or by hospitals with which they have contracted to such members of the public as become subscribers to said plans under contracts which entitle each subscriber to stated hospital care. S. 501 has passed the senate, proposing to authorize every county maintaining a hospital for the indigent to levy annually a tax not to exceed 4 mills on the dollar, to provide a special fund which is to be used, in addition to the amounts appropriated out of the general fund, for the maintenance of the hospital. S. 606 has passed the senate, requiring each county having a population of not less than 53,000 and not more than 57,000 to provide medical treatment, at county expense, to all indigent residents of the county infected with venereal disease. Each affected county is to be authorized to employ and pay at hourly rates of compensation determined by the board of county commissioners as many physicians as are necessary to provide the treatment required. Such boards are further directed to employ in rotation for periods of not less than six months all the resident physicians who have signified their willingness to undertake and perform such services at the prices set by the boards.

Bills Introduced.—S. 593 and H. 965 propose to establish in Seminole County a branch of the Florida State Hospital, for the care and treatment of insane persons. H. 869 authorizes the performance of autopsies on deceased patients of the Florida State Hospital who have no surviving relatives or guardians, or in instances in which the superintendent of the hospital is unable to get in touch with relatives or guardians of deceased patients to procure consent. S. 624 and H. 1092 propose to regulate the manufacture, sale, distribution and advertising of foods, drugs, cosmetics and devices.

Illinois

Bills Introduced.—S. 467 proposes to prohibit any person from practicing as a consulting psychologist without a certificate of registration as provided for by the bill. A person to receive such certificate must have received a degree either of Doctor of Philosophy in psychology, Doctor of Science in psychology, Doctor of Education, or Doctor of Philosophy in education from an approved school, must have had two years' experience in the application of the principles and technics of the science of psychology and must pass examinations to be given by an examining committee consisting of five psychologists. H. 977 proposes to authorize the organization of corporations to operate nonprofit medical service plans whereby medical care or medical and hospital service may be provided by the corporations to those persons who become subscribers to the plans under contracts which entitle each subscriber to stated medical care. Any nonprofit medical plan so established is to entitle each subscriber to select a physician of his own choice.

Massachusetts

Bills Introduced.—H. 2265 proposes to require a physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample to a laboratory approved by the department of public health for a standard serologic test for syphilis. H. 2281 proposes to require each party to a proposed marriage, as a condition precedent to obtaining a license to marry, to present a certificate signed by a registered physician who has examined the party. If the physician in making the examination discovers evidence of any infectious disease declared by the state department of public health to be dangerous to the public health, he must inform both parties as to the nature of the infectious disease discovered and the possibilities of transmitting it to the marital partner or to their children. The examination by the physician must include a standard serologic test for syphilis.

Missouri

Bill Amended in the Senate.—S. 342 was so amended in the senate May 15 as to provide that the State Board of Health, which the bill proposes to designate as the agency to handle all funds appropriated for public health by the state or granted for such purposes by the federal government, in carrying out the duties imposed on it in that connection must give equal rights and privileges to all licensed practitioners of any school of medicine or healing recognized by the laws of the state.

New York

Bills Passed.—S. 2255 has passed the assembly and the senate, proposing so to amend the laws relating to the practice of osteopathy as to provide that any licensed osteopath or any applicant for such license "who upon the submission of proper credentials or by examination satisfies the regents that he has received sufficient instruction and training, may be granted the right to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics and biological products." S. 2257 has passed the senate and the assembly, proposing so to amend the insurance code as to permit the organization of cooperative corporations to furnish medical expense indemnity or hospital service to persons who become subscribers under contracts with such corporations.

Pennsylvania

Bill Passed.—S. 1031 passed the senate May 18, proposing to appropriate $20,000 to the Department of Health for the use of the Land Grant College of Pennsylvania to advance research in nutrition for children.

Bills Introduced.—S. 1003 proposes to create a healing art advisory board to advise the Secretary of Health with respect to the administration of the program of medical care to the indigent sick. The advisory board is to consist of one representative selected by each of the following: Department of Welfare, Department of Public Assistance, the Medical Society of the State of Pennsylvania, the state osteopathic association, the homeopathic medical society of the state, the state nurses' association, the state dental society, the state pharmaceutical association and the hospital association of the state. The bill also proposes to require the Department of Health to provide medical care to indigent persons certified by the Department of Public Assistance. S. 788 proposes to appropriate $25,000 to the State Department of Health for the use of the University of Pennsylvania School of Dentistry to carry on research in determining the cause and prevention of dental caries.

Wisconsin

Bills Introduced.—A. 823 proposes to appropriate a sum, sufficient together with moneys to be received by the state as federal aid, to distribute serums and antitoxins free of charge to persons in need of them and unable to afford them. A. 844 proposes to create an interim committee on the cost of medical care to consist of two senators and three assemblymen. This committee is to investigate the general subject of the cost of medical care and the ways and means of lightening the alleged burden thereof.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 2219.

ALABAMA

Regional Meeting.—At a meeting of the Northwestern division of the Medical Association of the State of Alabama, June 1, the following program will be presented:

Dr. Robert A. Berry, Birmingham, Fistula-in-Ano: Underlying Anatomical Factors.
Dr. Benjamin Hughes Kennedy Jr., Birmingham, Vomiting in Early Infancy.
Dr. Otis E. Marler, Carbon Hill, Abruptio Placenta, with Report of Five Cases.
Dr. James B. McLester, Birmingham, Rational Treatment of Myocardial Failure.
Dr. Lloyd Noland, Fairfield, Management of the Thyroid Patient.

ARKANSAS

Course in Obstetrics.—Dr. H. Close Hesseltine, assistant professor of obstetrics and gynecology, Department of Medicine, Division of Biological Sciences, University of Chicago, will conduct a course in obstetrics in Arkansas in cooperation with the state board of health, U. S. Children's Bureau and the committee on maternal and child welfare of the society. The series of weekly lectures will open in Prescott May 29 to continue for six weeks. Similar programs will be conducted in McGehee, beginning May 30; Jonesboro, beginning May 31; Conway, June 1; Fort Smith, June 2.

COLORADO

Appointments Made to Health and Examining Boards.—Dr. Ray L. Drinkwater, Charles G. Grover, D.D.S., and Attorney Joseph A. Myers, all of Denver, were appointed to six year terms on the Colorado State Board of Health recently. The appointments, as required by law, were confirmed by the state senate before becoming effective. The three new members will succeed Dr. Charles A. Davlin, Alamosa; Dr. Ben Beshoar, Trinidad, and H. C. Dolph, D.D.S., Denver, whose terms had expired. This is the first time an attorney has served as a member of the state board. The two osteopathic members of the state board of medical examiners whose terms had expired, Rodney Wren, Pueblo, and C. Robert Starks, Denver, were reappointed by Secretary of State George E. Saunders. Dr. George R. Buck, Denver, was appointed to succeed Dr. Nolie Mumey, Denver, whose term expired this year. Later Governor Carr reappointed the two osteopathic members but appointed Dr. Orland P. Shippey, Saguache, to succeed Dr. Mumey. The state senate took no action with regard to these appointments as there has been no apparent requirement in the law for senate confirmation of appointments to this board, but the state executive council, by a straight party vote, approved Secretary Saunders' appointments. According to the Rocky Mountain *Medical Journal*, it is the evident intention of state officials to bring about a legal test case, to which Drs. Buck and Shippey would be the nominal parties at suit, to determine where the power of appointment lies under the existing administrative code.

CONNECTICUT

Dr. Clendening Lectures at Yale.—Dr. Logan Clendening, professor of clinical medicine, University of Kansas School of Medicine, Lawrence-Kansas City, delivered the Beaumont lecture on the history of medicine at Yale University School of Medicine, New Haven, April 21. His subject was "Medicine in Paris at the Time of Oliver Wendell Holmes' Visit." Dr. Ernest J. Caulfield, Hartford, president of the Beaumont Medical Club, introduced Dr. Clendening.

DISTRICT OF COLUMBIA

Library Given to Leonard Wood Memorial.—The library of Dr. Earl Baldwin McKinley, who lost his life on the Hawaii Clipper last summer, has been given by his wife to the Leonard Wood Memorial (American Leprosy Foundation), and will be placed in the Culion Library at Culion, P. I., the collection to constitute the "Earl Baldwin McKinley Memorial Library."

Personal.—Dr. J. Winthrop Peabody recently resigned his position as general superintendent of the District tuberculosis hospitals to devote his entire time to private practice.——Dr. Winfred Overholser, superintendent of St. Elizabeths Hospital, Washington, and formerly commissioner of the department of mental diseases of Massachusetts, was voted honorary membership in the Massachusetts Psychiatric Society March 24 in recognition of his many years of work for the advancement of psychiatry in the commonwealth.——Dr. Jefferson Davis Bradfield recently retired as diagnostician in the District health department; he had been connected with the department of psychiatry in the commonwealth.——Dr. Jefferson surgeon general, U. S. Public Health Service, sailed April 12 to attend medical conferences in Paris, Geneva and Scarborough, England; in Paris he attended the meeting of the Permanent Health Office April 23; in Geneva the Conference of the Health Committee of the League of Nations, beginning May 4, and in England he will attend the International Medical Congress, which opens July 1.

ILLINOIS

Dr. Baxter Appointed State Health Director.—Dr. Albert C. Baxter, acting director of the Illinois State Department of Health since the resignation of Dr. Frank Jirka in 1937, has been appointed head of the department, newspapers reported May 4.

Wanted — Unidentified Typhoid Carrier.—The state department of public health is trying to find an unidentified typhoid carrier somewhere in Illinois and thereby avert a possible outbreak of the disease. The state diagnostic laboratory received a specimen for examination for a typhoid carrier May 13 and it turned out to be positive. There was nothing to identify the source of the specimen. The postmark was not legible and the physician who sent the specimen failed to give his own name or that of the patient.

INDIANA

Postgraduate Course.—Indiana University School of Medicine conducted its annual postgraduate course April 10-15. General in scope, the program included clinics and clinicopathologic conferences. The guest speakers included Drs. Julian D. Hart, Durham, N. C., on infections; Morton D. Willcutts, Washington, D. C., subject not announced, and Wyman C. C. Cole, Detroit, "Etiologic Factors in Neonatal Asphyxia."

District Meetings.—Among others, Dr. Willis D. Gatch, Indianapolis, addressed the Second District Medical Society in Bloomington May 24 on "Endometriosis."——The speakers before the Fourth District Medical Society in Columbus May 25 included Dr. Arlie R. Barnes, Rochester, Minn., on "Important Principles in Treatment of Congestive Heart Failure."——Dr. Clinton W. Lane, St. Louis, discussed dermatology before a joint meeting of the Fifth District Medical Society, the Vigo County Medical Society, the Aesculapian Society of the Wabash Valley and the Terre Haute Academy of Medicine in Terre Haute May 5.——At a meeting of the Sixth District Medical Society in Connersville June 7, the speakers will include Drs. Harry V. Scott, Fort Wayne, on "Vomiting in the Newborn and Infancy"; Gerald F. Kempf, Indianapolis, "Newer Aspects of Treatment of Acute Infectious and Contagious Diseases" and William S. Robertson, Spiceland, "Electrocardiography in General Practice."——The Ninth District Medical Society was addressed in Lebanon May 11, among others, by Dr. Cyrus J. Clark, Indianapolis, on "Sulfapyridine in the Treatment of Pneumonia."——Among others, Dr. Howard M. Odel, Rochester, Minn., addressed the Eleventh District Medical Society in Peru May 10 on "Essential Hypertension—Diagnosis and Management."

KENTUCKY

Society News.—Drs. Will R. Pryor and Lytle Atherton addressed the Jefferson County Medical Society, Louisville, May 1 on "Sulfanilamide—Its Value in Infections of the Eye, Ear, Nose and Throat" and "Hydronephrosis" respectively.——Dr. Louis Wallace Frank addressed the Louisville Medico-Chirurgical Society May 12 on "Vitamin K in the Treatment of Upper Gastro-Intestinal Hemorrhage."——Speakers at a meeting of the Louisville Obstetrical and Gynecological Society May 22 were Drs. Henry M. Rubel on "Sulfanilamide in Obstetrics and Gynecology" and Nora D. Dean, "Anesthesia in Gynecology and Obstetrics."——Drs. Elmer L. Henderson,

Louisville, and Oren A. Beatty, Glasgow, addressed the Third District Medical Society, Bowling Green, March 15 on "Hysterectomy" and "Ambulatory Bilateral Pneumothorax" respectively.

Personal.—The McCracken County Health Department dedicated new headquarters in Paducah April 11 to Dr. Van A. Stilley, Benton, honoring his long years of service in the field of public health in western Kentucky. Dr. Carl C. Howard, Glasgow, delivered the principal address. A photomural of Dr. Stilley and a bronze plaque bearing the dedicatory inscription were hung in the building. Dr. Stilley is 72 years old and graduated from the University of Louisville School of Medicine in 1890. He is associate director of county health work for western Kentucky, is councilor for the first district of the state medical association and president of the Bank of Benton.——Dr. Andrew B. Steele, Lewisburg, Pa., has been appointed clinical director of the Western State Hospital, Hopkinsville.——Dr. Walter O. McCammon, Springfield, has been appointed health officer of Washington County to succeed the late Dr. William R. Thompson.——Dr. Isham Kimbell, clinical director at the Veterans Administration Facility, Lexington, has been transferred to the facility at Gulfport, Miss. ——Dr. Charles M. Smith, Dixon, has resigned as health officer of Webster County.——Dr. James W. Baird, Sadieville, was honored by the Scott County Medical Society with a dinner at Lancaster May 4, marking his fiftieth anniversary of medical practice.

LOUISIANA

State Medical Election.—Dr. Christian Grenes Cole, New Orleans, was chosen president-elect of the Louisiana State Medical Society at its annual convention in Alexandria April 26 and Dr. Clarence A. Lorio, Baton Rouge, was installed as president. Other officers are Drs. Dorman B. Barber, Alexandria, Edwin L. J. Zander, New Orleans, and Jean P. Mauboules, Rayne, vice presidents, and Paul T. Talbot, New Orleans, secretary-treasurer. The 1940 meeting will be held in New Orleans.

MASSACHUSETTS

Personal.—Dr. Curtis T. Prout, formerly of Wallingford, Conn., has been appointed medical director of the Ring Sanatorium and Hospital, Arlington Heights, succeeding Dr. Hosea W. McAdoo.——Dr. Salomon Gagnon, Waltham, assistant superintendent of the Metropolitan State Hospital, has been appointed chief executive officer of the Boston Psychopathic Hospital; he was succeeded at the Metropolitan by Dr. William Corwin.——A buffet supper and reception was recently given to honor Dr. Marion Nute in recognition of his completion of forty years as a member of the staff of the New England Hospital for Women and Children.

Symposium on Virus and Rickettsial Diseases.—A short course of lectures, clinics and demonstrations on the virus and rickettsial diseases, with special emphasis on their public health significance, will be presented at the Harvard School of Public Health, Boston, June 12-17. The fee for the course will be $25, payable at any time up to June 12. Enrolment should be arranged before June 1, as facilities for many of the clinics and demonstrations are limited. The lectures will be published later in a single volume, which will be sent to each person who registers for the course. Further information may be obtained from the secretary of the school of public health, 55 Shattuck Street, Boston. Members of the symposium committee are Drs. LeRoy D. Fothergill, chairman, Cecil K. Drinker, John E. Gordon, Edward G. Huber, Charles F. McKhann and Philip Drinker, Ch.E.

MINNESOTA

State Medical Meeting at Minneapolis.—The eighty-sixth annual session of the Minnesota State Medical Association will be held in Minneapolis May 31-June 2, under the presidency of Dr. George A. Earl, St. Paul. Out of state speakers will include:

Dr. Rock Sleyster, Wauwatosa, Wis., President, American Medical Association.
Dr. Andrew C. Ivy, Chicago, Bile Salt Therapy in Gallbladder Disease.
Dr. Joseph Stokes Jr., Philadelphia, Studies of Certain Respiratory Infections of Virus Origin.
Dr. Charles L. Scudder, Boston, Fractures as a State Medical Association Problem.
Dr. Everett D. Plass, Iowa City, Treatment of Vaginal Discharges.
Dr. Thomas Francis Jr., New York, Diagnosis of Virus Diseases.
Dr. Robert G. Bloch, Chicago, Unsuspected Pulmonary Tuberculosis.

One feature of the program will be a conference on medical problems in Minnesota with the following speakers: Drs. Clifford E. Waller, U. S. Public Health Service, Washington, D. C.; Frederick W. Jackson, Winnipeg, Man.; William A. O'Brien, Minneapolis, and Monsignor Maurice F. Griffin, Cleveland. Many scientific motion pictures will be shown during the session. The first public health exposition ever sponsored by the state association will open in the auditorium basement Wednesday May 31 and close Saturday June 3. The annual award of the Southern Minnesota Medical Association will be presented at the annual banquet at the Hotel Curtis Thursday evening. Twenty round table luncheons have been planned. The Minnesota Radiological Society will hold a dinner May 31 in honor of Dr. William Edward Chamberlain, Philadelphia, who will deliver the Russell D. Carman Memorial Lecture May 30. His subject will be "Low Back Pain." Dr. Bloch will address the Trudeau Society at a dinner meeting May 31 on "Tuberculous Caseation, Excavation and Calcification."

MISSOURI

Conference for Negro Physicians.—Announcement is made that a conference for Negro physicians, to be known as the Medical Institute for Physicians, will be held annually under the joint auspices of the Tuberculosis and Health Society of St. Louis, the Mound City Medical Forum and the St. Louis Health Department. The first session was held at the Homer G. Phillips Hospital, St. Louis, April 19-21, and covered discussions in the new developments in diagnosis, treatment of tuberculosis and syphilis and child and maternal hygiene. One evening session, open to the public, was a symposium on health and disease.

MONTANA

Changes in State Board.—Dr. George F. Turman, Missoula, was named chairman of the state board of health, succeeding Dr. Enoch M. Porter, Great Falls, at the board's semiannual meeting in Helena April 6. Dr. Louis H. Fligman, Helena, was named vice president.

Personal.—Dr. E. Martin Larson, Great Falls, for many years president of the Montana Tuberculosis Association, was reelected for another one year term at the twenty-third annual meeting of the association in Helena April 8.——Dr. Harry A. Crecelius, Plains, has been appointed physician and health officer of Sanders County, according to the *Journal-Lancet*.

NEBRASKA

Physician Honored.—The Seward County Medical Society and the Sixth Councilor District Medical Society held a dinner in Milford in honor of Dr. and Mrs. Charles W. Doty, Beaver Crossing, April 10. According to the state medical journal, Dr. Doty is the oldest member of the district and has practiced in Seward County since his graduation from Rush Medical College in 1888. Dr. Joseph Morrow, Seward, was toastmaster.

Society News.—The Five County Medical Society was addressed in Wayne April 6 by Dr. Wayland K. Hicks, Sioux City, on "Bladder Tumors" and Dr. Arthur L. Miller, Kimball, member of the legislature, discussed medical legislation. ——Dr. Rex L. Murphy, Denver, addressed the Scottsbluff County Medical Society in Scottsbluff April 13 on "Chest Conditions of Special Interest to the Otolaryngologist."——Drs. Charles W. McLaughlin Jr. and John W. Duncan addressed the Omaha-Douglas County Medical Society April 11 on "The Acute Surgical Abdomen in Infancy and Childhood" and "Diagnosis and Treatment of Esophageal Diverticula" respectively.——Drs. Arthur D. Munger and Rufus A. Lyman, adddressed the Lancaster County Medical Society, Lincoln, March 7 on "Rational Use of Intravenous Solutions" and "Trends in Professional Education" respectively.

NEW YORK

Outbreak of Gastro-Enteritis.—According to *Health News*, an outbreak of gastro-enteritis in a village in Chautauqua County in March was attributed to failure of the chlorinator to operate during a period of thaw and high water when the source of supply was particularly susceptible to surface pollution. Sixty persons were known to be affected. The onset of illness was sudden and characterized by nausea, abdominal distress and fluid stools. Fever was noticed in about one fifth of the cases. The illness lasted usually from one to three days. All patients recovered.

New York City

The Janeway Lecture at Mount Sinai.—Max Bergmann, Ph.D., member of the Rockefeller Institute for Medical Research, delivered the Edward Gamaliel Janeway Lecture at Mount Sinai Hospital May 16. His subject was "Some Biological Aspects of Protein Chemistry."

Harlow Brooks Memorial Meeting.—The Washington Square Medical Society held its annual Harlow Brooks medical program April 20. Dr. Louis F. Bishop opened the session with "Reminiscences of Dr. Harlow Brooks" and Dr. Lewellys F. Barker, Baltimore, delivered the memorial lecture on "The Diagnosis and Treatment of Vitamin Deficiencies."

Conferences on Tuberculosis—The modern methods of diagnosis and treatment of tuberculosis is the theme of a series of four evening conferences for physicians which opened at the East Harlem Health Center May 11 to continue through June 1. The physicians of the district are invited to bring their own cases and roentgenograms to the conferences for discussion.

Society News.—The New York Diabetes Association held a clinical meeting April 28; the speakers were Drs. John S. Lockwood, Philadelphia, "Treatment of Streptococcus Infections in Diabetes Mellitus with Sulfanilamide"; Frank L. Meleney, New York, "Treatment of Anaerobic Infections in Diabetes Mellitus with Zinc Peroxide," and Valentine M. Murray Wright, Philadelphia, "Diabetic Surgery."

Dr. Park Leaves Bequest for Research.—A fellowship fund for research in medicine, clinical work and bacteriologic and filtrable virus diseases will be established with the residuary estate of Dr. William H. Park, whose will was filed for probate April 10. Dr. Park died April 6. The fund is to continue in perpetuity and is to be called the William Hallock Park Research Fund. Disbursements will be made by a committee composed of the deans of New York University College of Medicine, Cornell University Medical College and Columbia University College of Physicians and Surgeons, Dr. Camille Kereszturi and Dr. Bela Schick. The value of the estate was not determined.

NORTH CAROLINA

Society News.—Dr. Douglas H. Sprunt, Durham, addressed the New Hanover County Medical Society April 20 on "Increased Resistance to Infections Produced by Certain Endocrine Systems."——Dr. Richard M. Pollitzer, Greenville, S. C., among others, addressed the Thermal Belt Medical Society in Marion April 20 on "Pediatric Case Records."——Dr. Julian Deryl Hart, Durham, addressed the Lenoir County Medical Society, Kinston, April 14 on diseases of the parathyroid glands.

Personal.—The Wayne County Medical Society devoted a meeting April 4 in Goldsboro to honoring three members who have practiced for fifty years or more. They were Drs. William H. Cobb and William J. Crawford, Goldsboro, and William G. Sutton, Seven Springs. Dr. Hubert A. Royster, Raleigh, was the principal speaker, reviewing changes in medicine during the past century.——Dr. Millard B. Bethel, Statesville, has been appointed health officer of Cabarrus County, succeeding Dr. John S. Anderson, who resigned.

Asheville Hospital Given to Duke University.—Dr. Robert S. Carroll, founder, owner and medical director of Highland Hospital for nervous and mental disorders, Asheville, has presented the hospital to Duke University, Durham, to be developed as the therapeutic unit of a new department of psychiatry. If at any time in the future the university decides that operation of the hospital in Asheville is not practicable, the property and equipment may be disposed of, but the proceeds therefrom must be used to advance the specialty of psychiatry at Duke. Dr. Carroll will remain the hospital medical director for five years, during which time a gradual interchange of personnel between the institutions will be effected. Highland Hospital, founded in 1904, has a capacity for sixty-five patients. It has three principal buildings, one of which is now being replaced by a stone structure which will have 100 rooms, according to a newspaper account. It is surrounded by fifty acres of specially developed land and 400 acres of mountain woodland, also used by the institution. Included in the gift is Dr. Carroll's residence, which may be used for a faculty residence and assembly hall. Dr. Carroll took medical degrees from Marion Sims College of Medicine in 1893 and from Rush Medical College, Chicago, in 1897. He is 70 years old.

OHIO

New Building at Jewish Hospital.—The dedication of the new building to house the May Institute for Medical Research of the Jewish Hospital, Cincinnati, will take place May 29. Dr. Moses Salzer will preside. Mr. Leo Lehman will present the building to the hospital on behalf of Mrs. David May, and Mr. Maurice E. Pollak, president, board of trustees, will give the speech of acceptance. Dr. Albert H. Freiberg, president of the medical staff, will speak on "Research and Practice in the Hospital"; Dr. Alfred Friedlander, dean, University of Cincinnati College of Medicine, "Truth and Research," and Dr. Anton J. Carlson, professor of physiology, Division of Biological Sciences, University of Chicago, "Science and the Common Life."

PENNSYLVANIA

District Meeting.—The annual meeting of the Seventh Councilor District Medical Society was held in Williamsport April 14. On the scientific program Dr. Russell S. Boles, Philadelphia, made an address on "A Consideration of Functional and Organic Diseases"; Drs. Lloyd G. Cole, Blossburg, and Louis L. Hobbs Jr., Ridgway, "Tumors of the Thyroid Gland." Dr. Rosco G. Leland, Chicago, director, Bureau of Medical Economics, American Medical Association, spoke at the afternoon session on "Current Problems in Medical Care." Other speakers were Drs. David W. Thomas, Lock Haven, president, and Chauncey L. Palmer, Pittsburgh, chairman of the committee on public health legislation of the Medical Society of the State of Pennsylvania; Alexander H. Stewart, deputy secretary, state department of health, and Mrs. Walter F. Donaldson, Pittsburgh, president of the woman's auxiliary of the state medical society.

Pittsburgh

The Bedford Lecture.—The Hon. Samuel B. Pettengill, former Congressman from Indiana, delivered the annual Bedford Lecture of the Allegheny County Medical Society April 27 on "The Citizen's Interest in the Threatened Socialization of Medicine."

Society News.—At the annual meeting of the Pittsburgh Surgical Society at the Mellon Institute May 26 the speakers were Drs. John Stewart Rodman on "Circulatory Problems of Surgical Importance in the Diagnosis of Abdominal Lesions"; Isidor S. Ravdin, "Some Surgical Problems of the Extrahepatic Bile Passages," and Melvin S. Henderson, Rochester, Minn., "Delayed Union and Nonunion in Fractures."

SOUTH DAKOTA

Personal.—Dr. Burt A. Dyar, Pierre, has been appointed full time secretary of the state interallied professional council, which represents the medical, dental, nursing, hospital and pharmaceutical associations.——The South Dakota Public Health Association has changed its name to the South Dakota Tuberculosis Association.

State Medical Election.—Dr. Oscar J. Mabee, Mitchell, was chosen president-elect of the South Dakota State Medical Association at its annual meeting in Aberdeen April 24-26 and Dr. John C. Shirley, Huron, was installed as president. Dr. Bertrand M. Hart, Onida, was named vice president. The next annual session will be in Watertown. The society decided at the recent meeting to redefine the boundaries of the twelve districts as follows:

District number 1, Aberdeen; McPherson, Marshall, Brown, Edmunds, Faulk and Spink counties.
District number 2, Watertown; Clark, Codington, Hamlin and Duel.
District number 3, Madison; Brookings, Lake, east half of Kingsbury and east half of Miner.
District number 4, Pierre; Ziebach, Armstrong, Potter, Sully, Hyde, Hughes, Lyman, Jones, Stanley, Haakon and Jackson.
District number 5, Huron; Hand, Beadle and west half of Kingsbury.
District number 6, Mitchell; Buffalo, Jerauld, Sanborn, west half of Miner, west half of McCook, Hanson, Davison, Aurora and Brule.
District number 7, Sioux Falls; Minnehaha, Lincoln, and east half of McCook, and Moody.
District number 8, Yankton; Charles Mix, Douglas, Hutchison, Bon Homme, Yankton, Turner, Clay and Union.
District number 9, Black Hills; Harding, Butte, Meade, Lawrence, Pennington, Custer, Fall River, Washington, Shannon, Washabaugh and Bennett.
District number 10, Rosebud; Mellette, Todd, Tripp and Gregory.
District number 11, Northwest; Perkins, Corson, Dewey, Walworth and Campbell.
District number 12, Whetstone Valley; Day, Roberts and Grant.

TENNESSEE

Graduate Course in Internal Medicine.—Vanderbilt University School of Medicine, Nashville, will conduct a graduate course in internal medicine to extend over a period of one year, beginning July 1. Limited to six students, the course will consist of supervised work with patients in the medical outpatient service, including the related specialties; experience in the diagnostic laboratories; assigned reading, seminars and conferences, including pathologic and radiologic conferences and autopsy study; directed study and seminars in the preclinical sciences, particularly physiology and biochemistry. Special investigation of a particular problem in one of the divisions of internal medicine as the basis of a thesis will be required. The course will be open to physicians who have completed an internship, have had an additional year's experience as assistant resident in medicine or its equivalent and are acceptable to the school. Three fellowships are available for this course, providing tuition, board and lodging. Additional information may be obtained from the director of postgraduate instruction, Vanderbilt University School of Medicine, Nashville.

GENERAL

Inspection of Airplanes for Insects.—The U. S. Public Health Service reported in *Public Health Reports* April 7 that 398 aircraft were inspected last year for possible mosquito infestation. Of this number, 187 were harboring dead and live insects of various species. A total of 651 insects were recovered, 166 of them alive. Forty were mosquitoes, but only five were alive. None of the mosquitoes was of a dangerous species. Inspection is carried out on all incoming aircraft from Mexico, South America, the Canal Zone and the West Indies primarily for the purpose of detecting mosquitoes that might carry yellow fever. The airline employees spray the planes to kill insects before landing at any port and on overnight stops the planes are thoroughly sprayed after disembarkation of passengers and crew and the planes are closed for the night. The routine inspections are performed by entomologists of the public health service with a flashlight and a chloroform tube.

Teachers of Sight-Saving Classes.—The National Society for the Prevention of Blindness is cooperating with the following colleges and universities in offering at their summer sessions courses for teachers and supervisors of sight-saving classes:

Western Reserve University, Cleveland, June 19 to July 28.
State Teachers College, Buffalo, N. Y., June 26 to August 4.
State Teachers College, Milwaukee, June 26 to August 4.
University of California at Los Angeles, June 26 to August 4.
Wayne University, Detroit, Mich., June 26 to August 4.

Details may be obtained from the university or college.

Dr. Whipple Wins Kober Medal.—Dr. George H. Whipple, professor of pathology and dean, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., was presented with the George M. Kober Medal at the annual meeting of the Association of American Physicians at its meeting in Atlantic City, May 3. Dr. Whipple is noted for research on metabolism, blood regeneration and treatment of secondary anemias. With Drs. George R. Minot and William P. Murphy, Boston, Dr. Whipple several years ago shared the Nobel Prize in medicine for research on pernicious anemia. The Kober Medal is an outstanding award, endowed by the late Dr. George M. Kober, Washington, D. C.

Special Society Elections.—Dr. Herbert B. Wilcox, New York, was elected president of the American Pediatric Society at its recent annual meeting. Dr. Hugh McCulloch, St. Louis, was reelected secretary.——At the annual meeting of the American Physiological Society in Toronto April 28 Dr. Andrew C. Ivy, Chicago, was elected president, and Philip Bard, Ph.D., Baltimore, reelected secretary.——Dr. Ernest W. Goodpasture, Nashville, Tenn., was chosen president of the American Society for Experimental Pathology at its annual meeting in Toronto April 28; Dr. Shields Warren, Boston, vice president, and Dr. Paul R. Cannon, Chicago, secretary. ——At the annual meeting of the American Society for Pharmacology and Experimental Therapeutics in Toronto April 27 Dr. Oscar H. Plant, Iowa City, was designated president. Dr. Gustave Philip Grabfield, Boston, was reelected secretary. Dr. Plant was also elected president of the Federation of American Societies for Experimental Biology and Dr. Donald R. Hooker, Baltimore, reelected secretary.——Dr. Isaac Starr, Philadelphia, was chosen president of the American Society for Clinical Investigation at its annual meeting in Atlantic City May 1 and Dr. Eugene M. Landis, Philadelphia, secretary.

Registration Under Harrison Narcotic Act and the Marihuana Tax Act.—On or before July 1, every physician registered under the Harrison Narcotic Act or under the Marihuana Tax Act, or under both, must reregister with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to reregister within the time allowed by law adds a penalty of 25 per cent to the annual tax payable at the time of registration and in addition makes the physician in default liable to a fine not exceeding $2,000, or to imprisonment for not exceeding five years, or to both. The Commissioner of Internal Revenue has been lenient in the past in enforcing the criminal penalties for tardy registration but continued disregard on the part of some physicians of the requirement with respect to reregistration will inevitably lead to criminal prosecutions. In recent years the commissioner has given some negligent or recalcitrant physicians the choice between paying substantial sums by way of compromise in lieu of the penalties for their offenses or, as an alternative, accepting criminal prosecution with resultant publicity and liability to fines and possible imprisonment. This was an act of grace on the part of the commissioner; he might have instituted criminal prosecutions without allowing the offending physicians any choice in the matter. If the course that the commissioner has adopted does not produce the desired promptness in registration, he will have no recourse other than criminal prosecution.

Gastro-Enterologic Meeting.—The fourth annual convention of the National Gastroenterological Association will be held at Squibb Hall, New York, June 1-2, under the presidency of Dr. Anthony Bassler, New York. The speakers will include:

Drs. John Stewart Rodman and William G. Leaman Jr., Philadelphia, Role of Circulatory Disorders in the Diagnosis of Lesions of the Gastrointestinal Tract.
Dr. James J. Hepburn, Boston, A Consideration of the General Problem of Gastric and Duodenal Ulcer.
Dr. Hubley R. Owen, Philadelphia, Causes of Poor Results in the Operative Treatment for Duodenal Ulcer.
Dr. Samuel A. Loewenberg, Philadelphia, The Anemias versus Gastrointestinal Disease.
Drs. Isidor S. Ravdin and Jonathan E. Rhoads, Philadelphia, The Control of Hemorrhage in the Jaundiced Patient.
Drs. Max Einhorn and Otto C. Pickhardt, New York, Report of a Case of Segmental Jejuno-Ileitis.
Dr. Charles L. Brown, Philadelphia, Disorders of Calcium Metabolism in Diseases of the Gastrointestinal Tract.
Dr. Frank W. Konzelmann, Philadelphia, An Evaluation of Liver Function Tests.
Dr. George W. Papen, Boston, Conservatism in Surgery of the Pancreas.
Drs. John F. McCloskey and James A. Lehman, Philadelphia, The Surgical Management of Acute Cholecystitis.
Dr. Bernard Fantus, Chicago, The Therapy of Colon Stasis.
Dr. Ellis B. Freilich, Chicago, Gastrointestinal Tuberculosis.
William Walter Cort, Ph.D., and Gilbert Fred Otto, Sc.D., Baltimore, Immunity in Hookworm Disease.
Dr. Myer Solis-Cohen, Philadelphia, Gastrointestinal Disturbances Due to Bacterial Toxemia from Focal Infection.
Dr. Cyrus W. Strickler, Atlanta, Ga., Congenital Bands and Adherences—Symptomatology and Treatment.
Dr. Moses Behrend, Philadelphia, Primary and Recurrent Obstruction of the Common Duct.
Drs. Isaac R. Jankelson, Boston, and Samuel Morein, Providence, R. I., Complications of Diaphragmatic Hernia.
Dr. George G. Miller, Montreal, Canada, Demonstration of Gastric Resection (motion picture).
Dr. Bela Halpert, New Orleans, Gallbladder Disease and Gallstones (by title).

On Wednesday May 31 the first of a series of annual lectures will be delivered at a reception in the Professional Building, New York World's Fair, by Dr. Max Einhorn, New York, on "The Behavior of the Physician Toward His Patient and His Profession."

Association for Advancement of Science.—The American Association for the Advancement of Science will meet in Milwaukee, June 19-24. The program for the Section on Medical Sciences (N) at Marquette University School of Medicine will include thirty-three papers, constituting a symposium on the gonococcus and gonococcic infections sponsored by the American Neisserian Medical Society and Section N. Among the speakers will be:

Dr. Elston L. Belknap and Margaret C. Perry, Milwaukee, Correlation of Clinical Findings with Results from Over 800 Quantitative Lead Examinations of Urine.
Dr. Armand J. Quick, Milwaukee, The Prothrombin Concentration in the Blood of Newborn.
Dr. Michael [illegible], Biological Preparations for the Treatment [illegible]
Dr. Wesley [illegible] hogenesis of Gonococcic Infection.
Drs. Oscar F. Cox Jr. and William A. Hinton, Boston, Evaluation of Smear and Cultural Methods for Detecting the Gonococcus in Males Treated w[illegible]
Dr. Sara E. [illegible], D. C., Gonococcic Meningitis.
Dr. Ralph R. [illegible] E. Shinn, Ph.D., Pittsburgh, Pa., The Mode of Action of Sulfanilamide with Special Reference to Its Anticatalase Property.
Dr. Russell D. Herrold, Chicago, Comparative Efficacy of Sulfanilamide and Sulfapyridine in the Treatment of Gonococcic Infection.

Antitoxins Prepared for War Use

At the request of the government the Medical Research Council has made arrangements to provide antitoxins in a quantity sufficient to insure their continued supply in the event of war.

TETANUS ANTITOXIN

Tetanus antitoxin has been provided for both prophylactic and therapeutic use. The prophylactic dose is 3,000 international units (1,500 American units) and is contained in a volume not exceeding 3 cc. During the early part of the great war 500 American units was administered as a routine and produced a striking effect in reducing the incidence of tetanus. During the later stages of the war attempts were made to reduce further the low incidence of tetanus by repeating the dose or increasing it. Since the war the tendency has been to administer 1,000 and, more recently, 1,500 American units. It has been decided that if the prophylactic use of tetanus antitoxin is again required, the dose shall be at this higher level of 1,500 American units. For the treatment of tetanus, ampules of antitoxin containing not less than 10,000 American units in a volume not exceeding 8 cc. have been prepared.

GAS GANGRENE ANTITOXIN

While it is generally recognized that early and adequate surgical treatment is the most important measure in the treatment of gas gangrene, opinion is divided as to the value of antitoxin in the prophylaxis and treatment. It is generally regarded as an accessory to surgical treatment. There are difficulties in the production of antitoxin arising from uncertainty as to the spore-bearing anaerobes concerned and doubt as to whether the predominating organism is the same in urban as in rural districts and whether the antitoxin should be given to all casualties or restricted to those which war experience has shown are likely to have gangrene. Moreover, little is known as to the proper dose. In civil life the infection is more often due to the Welch bacillus than to other anaerobes, such as vibrion septique and Clostridium oedematiens.

Stocks of Welch bacillus, vibrion septique and Clostridium oedematiens antitoxins have been acquired which are considered to be adequate for the needs of both the defense services and the civil population, for both prophylaxis and treatment. Modern preparations of gas gangrene antitoxin are of greater potency than those used in the great war. The arrangements made allow for administration of the antitoxins separately or combined, and the injection can be combined with tetanus antitoxin. The provisional doses (which may be modified in the light of experience or to meet special circumstances) are 3,000 units of Welch bacillus, 1,500 of vibrion septique and 1,000 of Clostridium oedematiens antitoxin, respectively, as a combined injection for prophylaxis. For treatment the dose is two and one-half times as great.

The Epidemiology of Jaundice

At the Royal Society of Medicine Dr. E. R. Cullinan, opening a discussion on the epidemiology of jaundice, said that two forms of infective jaundice, Weil's disease and common infective jaundice, were seen in this country. The former, defined by Weil in 1886, was still relatively uncommon, less than 200 cases having been reported in Great Britain. The disease in human beings could almost always be traced to rats, the organism entering through cuts and sodden skin or perhaps through the conjunctiva and upper respiratory tract. Early diagnosis was essential, as antiserum was valuable in the first stage. There were mild infections without jaundice characterized by fever and malaise, and the disease should be suspected if the patient's occupation brought him into contact with rats.

Common infective, or catarrhal, jaundice was widespread; apparently catarrhal types were seen. Its cause was unknown. In the last twelve years 1,707 outbreaks, widely scattered, were reported in this country. Infectivity was low and incubation long. Children from 6 to 10 years old were peculiarly susceptible. There were often a prodromal period of lassitude and malaise and a sharp febrile onset without rigor. Early headache, anorexia, nausea and abdominal pain were common, and vomiting was often severe. Jaundice appeared at any time up to twelve days after the onset, first in the conjunctiva and then in the face and neck. It usually heralded the beginning of convalescence, but in cases of severe involvement might last three weeks or longer. In adults the liver might be 3 finger-breadths below the ribs. If histamine was injected and a piece of glass pressed on the resulting wheal, 1 van den Bergh unit (or more) of bilirubin in the blood would be revealed by a yellow color in the center. The eye could not detect less than 4 units. The stools were usually clay colored at some time but often contained bile during the jaundice.

The disease spread from person to person and not by water, milk or food. The family and dormitory spread suggested droplet infection. Infectivity was high only when contact was close. The period of incubation was difficult to assess but approximated from twenty-one to thirty-five days. Patients were infectious before they were jaundiced, but the period of infectiousness was short. The pathologic process was probably necrosis of liver cells, but fatal cases were rare. In Sweden epidemic jaundice seemed to have taken the form of acute necrosis of the liver. Subacute necrosis, unassociated with any drug or toxin, was by no means unknown in England. The bile epithelium was seldom destroyed, and there was no evidence of obstruction or inflammation of the bile ducts. The similarity to common infective jaundice suggested a common cause.

A Gas Mask for Infants

Dr. Le Mée and his collaborators have produced a device which permits the protection of young infants against war gas. The child is placed in the ordinary inspirator with a person provided with an isolating or filtering mask. A trough of zinc lined with cork receives the child, whose head is covered by a metallic arch. This is enclosed in a sac of impermeable fabric which has a window, through which the child can be watched. Of two connections, one receives the filtering cartridge of the mask and the other the tube of the mask. The aspirating movement of the wearer of the mask causes a current of air which passes through the sac enclosing the child; the expiration expels the vitiated air through the valve of the mask. If necessary the apparatus can be connected with a small oxygen tank, which enriches the air of the common atmosphere of the two persons utilizing the single mask. If, instead of the filtering mask, the isolating mask, with regeneration of air, is used, the same couplings can be arranged so as to connect the sac containing the child in the common circuit. The invention of Dr. Le Mée seems to have solved in a simple manner the difficult problem of safeguarding young infants against war gases.

Postage Stamps to Aid Venereal Disease Campaign

The board of administrators of the national post office department put on sale this year, as it did last year, a stamp to obtain money for the League of Public Morals and for the prevention of venereal diseases. The stamp portrays a woman, who stands for the republic, with an infant, who stands for the race, in her

arms and contains the inscription "Saving the Race." The value of each stamp is 90 centimes (9 cents), which is the postage of any letter in the country and the colonies plus a tax of 30 centimes (3 cents) for the league. One million stamps were sold last year.

National Congress of Tuberculosis

The work of the National Congress of Tuberculosis held at Lille April 11-13 was divided according to the subjects biology, clinical medicine, social medicine and miscellaneous matters. The biologic section was devoted to the study of the role and distinctive characteristics of tuberculous infection due to the bovine bacillus and the avian bacillus. In 11.2 per cent of 100 cases of human tuberculosis the infection was found to be of bovine origin. The highest percentage of tuberculosis of this origin was found in Scotland. It is rare in France, where milk is boiled as a rule. The clinical section was devoted to the purulent exudates of therapeutic pneumothorax and their treatment. Three categories were examined: (1) The puriform effusions, through aging, to which belong the cold pleural abscess and the bacteriologically infected effusions, (2) malignant pyothorax and (3) the septic pleurisies. Complications can be avoided by performing the pneumothorax as early as possible and by intrapleural chrysotherapy. For treatment, to the evacuation followed by lavages with iodized solutions, the use of vaccines, anatoxin and, above all, sulfamide compounds should be added. In case medical treatment fails, surgical treatment should be applied. Simple pleurotomy, proposed by Robert Monod, was debated. On the whole the debates were rich in ideas and documentation but were somewhat confused. This circumstance seemed to indicate room for further study of the question of empyemas. The work in social medicine was devoted to antituberculous prophylaxis through systematic community surveys.

Prevention of Malaria

Professor Marchoux, in a lecture at the Académie de médecine, discussed the prevention of malaria in Tunisia, where the disease is a menace. He considered only the disease itself and the treatment of patients and not the campaign against the anopheles, which was carried out at the same time by classic methods. He had studied particularly the "return" from the medicaments employed, that is the relation between the expense and the results obtained.

For five years, under controlled conditions, synthetic antimalaria drugs, for example "prémaline" (atabrine 0.1 Gm., quinoline 0.005 Gm. and plasmochin 0.005 Gm.), were administered twice a month to a yearly average of 27,000 patients of both sexes and of all ages. The results, calculated by means of antimalaria indexes, i. e. the number of parasites in the blood and the size of the spleen, were satisfactory. From 1936 to 1938 the index of plasmodia diminished from 4.3 to 0.1 per cent. The splenic index in children diminished from 67.0 in May and 33.4 in October 1936 to 9.9 and 1.3 for the same months in 1938. No phenomena of intolerance were observed. This part of the antimalaria campaign cost from 13 to 15 francs ($1.30 to $1.50) per patient, and it was concluded that the region, formerly much contaminated, was now one of the most healthful of countries. But, as with all methods based on therapeutics, this form of treatment does not render unnecessary those measures which are designed to destroy the anopheles and drain the land.

Neurosurgery

Prof. Clovis Vincent, appointed to the chair of neurosurgery which was recently established at the Faculty of Medicine of Paris, in his inaugural speech discussed the development of neurosurgery. He deplored the fate of patients of sixty years ago who suffered from tumors of the brain or spinal cord, as death without relief awaited them. The same fate was in store for patients suffering from facial neuralgia. The field of neurosurgery is not yet entirely satisfactory. Constant collaboration between physicians and neurosurgeons is important. The speaker called attention to the work of Macewen, who in 1879 performed the first operation in a case of tumor of the frontal lobe. But the founder of the science was Cushing, who devoted his life to the development of neurosurgery.

Experimental Adenomas of the Prostate

Prostatic adenomas have been said to be due to hormonal disequilibrium caused by testicular deficiency or by a disturbance of balance between the male and female hormones. Senility exhausts the first, and the second, the estrogenic hormones, thereafter without counterpart, provoke hypertrophy of the prostate.

Petit, Gley and Béraut investigated the effect of injections continued for from twelve to fifteen days of estrogen. These investigations, made on twelve dogs from 2 to 2½ months of age, as well as on controls, demonstrated an intensification of the activity of the urethral epithelium, on which the prostate depends embryologically, with intense budding and adenomatous formation in this small gland, which ordinarily doubles in volume. This augmentation was ascribable especially to the interstitial framework, but its significance remained distinctly adenomatous. The process was rapid but not lasting; it completely regressed as soon as the injections were omitted. The utricle did not seem to have been modified.

Excellent photomicrographs illustrate this work, which was presented at the Société médicale des hôpitaux of Paris. They show that the prostate accelerates its development until occasionally it acquires its characteristic structure and this development becomes in a way comparable to that of the adenoma. The authors point out that one cannot expect to produce in fifteen days a true prostatic adenoma but that it is important to have verified the isolated action of estrogen on an essentially male organ.

More Changes Affecting Medical Practice

Among the interesting changes affecting medical practice which have been reported recently are the measures taken to "secure the economic existence of physicians representing workingmen's associations." According to explanations by Reichs-Aerzteführer Dr. Wagner (deceased), when these measures were promulgated, the workingmen's group physician has duties that are not governed by definite hours of work. He can perform these strenuous duties only if he keeps himself physically fit and efficient. Everywhere in Germany the principle is in effect that every one at work receives a leave of absence for which he continues to be paid. Every physician should likewise be obliged to relax completely at least once a year and take leave of absence. Many physicians in the past had to forego a leave of absence because they could not afford either the loss of income or the expense of a substitute during their absence. Wagner said "Since Jews have been eliminated from the medical profession and consequently from participation as representatives of workingmen's associations, Germany's national organization of workingmen's group physicians can now devise new ways of distributing medical fees." Also during illness the necessity of making both ends meet caused many physicians in the past grave cares. In different parts of the country different ways have been tried in the past to solve this difficulty. These attempts, however, were not satisfactory. New decisions provide compensation for physicians connected with workingmen's associations for loss of time and income, and a minimum income for workingmen's group physicians.

Compensation will be paid if the physician interrupts his practice on account of leave of absence, illness, military service

or participation in postgraduate work. The maximum number of days for which a fee will be allowed for leave of absence within a year is twenty-eight. The daily fee paid to the single physician is 12 marks and to the married physician 15 marks plus 1 mark for every child under the age of 21 years supported by the father. Compensation is allowed for sickness if the physician has not been able to practice his profession for more than twelve consecutive days. A medical certificate of another physician is necessary. Examination by an expert can also be required before compensation for sickness is paid, the expense being assumed by the society of workingmen's group organizations. The sick physician must certify that he did not practice even occasionally during the time for which he asks compensation. Compensation for sickness is granted within the same calendar year for as many as eight weeks at the same maximum level as compensation for leave of absence. In case of military duties that prevent the physician from practicing his profession for more than seven days, the single man is paid 7 marks daily and the married man 10 marks, besides 1 mark for every child. Twenty-eight days is the limit. Compensation is also paid for participating in obligatory postgraduate work. These special fees, exclusive of those for postgraduate studies, are paid only to physicians whose income from group practice among workingmen has averaged 500 marks during the last four years.

Physicians admitted to practice in connection with workingmen's groups are guaranteed a minimum income of 1,000 marks quarterly in the form of an increase of group fees if their income is less than that. In these calculations the physician's entire income is computed, that derived from the different policyholders, including the income from benefit bureaus. All other income of the group physician and his wife is also figured, irrespective of its source. However, 500 marks of this income is not included in the computation. This increase of fees is granted only on special request. These regulations concern especially physicians who, on account of increasing age, cannot engage in group practice to the same extent as their younger colleagues. They also concern physicians who for other reasons have a small practice but who are obliged to hold themselves ready to serve and to make available the necessary arrangements for medical practice like other group physicians under more favorable economic conditions.

Another institution belongs in the same picture—the family adjustment fund. It was established in 1934, when the distribution of the entire compensation for group practice was transferred to the association of group physicians. This fund concerns itself with the payment of increases for physicians' children under the age of 21 years the amount of 50 marks a month beginning with the third child. At the same time, an adjustment fund for areas of economic distress was created. Out of this fund the fees of group physicians who practice in regions of great economic need without being able to assure their own economic subsistence from their medical income are increased to 6,000 marks annually.

These new measures are of a nature to influence greatly in the long run the economic life of the medical profession, since later on the question must be considered to what extent the private practice of physicians is to be taken into account in view of the principles set forth. The changes now affect only about 37,000 group physicians of the old reich; for their extension to Austria and the Sudetenland the necessary organization has not yet been effected. Perhaps they will serve beyond their present scope as patterns for other professions. The urgent need for the two adjustment funds mentioned is shown by the official report of the conditions of the rural sick fund. The increases referred to were obviously restricted to localities in which a physician could not maintain himself because of the small population. By means of the increases it was made possible not only to fill a large number of medical positions which otherwise would have remained vacant but also to preserve them. For example, in 1938 nine physicians in Baden, thirty-six in Bavaria, six in Mecklenburg, twenty-six in Lower Saxony, eighteen in East Prussia and twenty-three in the Rhineland received extra allowances of this kind. Since its inception, this adjustment fund has paid out more than 1 million marks to rural physicians in sparsely settled regions. At present more than 300,000 marks is annually paid for this purpose. Only in this way was it possible to prevent physicians from moving away from the country and permanently to improve the medical service of rural areas. These measures must also be based in the future on the assumption that the benefits of this fund are limited to those who are unable to bear the medical costs themselves. Efforts to include the whole rural population in this sick insurance are not officially approved.

What Dr. Wagner himself said about the ideals of the family physician is of interest. The ideal conception of the family physician is perhaps set by the family physician of former days, who was well informed not only in the methods of medicine taught at school but in the natural art of healing and who was likewise the leader, counselor and friend when the patient did not need his medical services. It is the duty of such a physician not only to cure his patient physically but to guide him mentally according to the principles of Nazi "weltanschauung." (Formerly it was unheard of for the physician to be active politically with his patients.) The patient is to remain free to choose his physician, but the aim is that every one register for the period of a year with a definite physician. The physician would be interested no longer in an individual achievement but in having as few sick patients as possible in families thus registered. He would be paid no longer for treating the sick but for keeping them well. The healthiest and happiest nation is not the one that has the finest and largest hospitals and similar institutions, but the one that needs the fewest hospitals because the physician takes prompt measures to prevent sickness. The new type of family physician is therefore essentially different from his predecessor. Not only the family by itself but the social environment must be known in order to understand the disease and the necessary healing methods. With these questions the good old family physician surely had nothing to do.

Besides, the demands made in Germany today by the economic conscription of manpower and by a political science with a socialistic ideology have set the physician new tasks. If, as is now the case, every worker is actually employed, it is doubly difficult for the physician to strike a proper balance between the necessary recreation of the worker and the urgency with which the work needs to be done. At the same time, the efficiency of the worker is to be heightened in accordance with an expressly promulgated objective of medical leadership and consolidated labor and preserved to a higher age level. Inspection of managements, the inclusion of the physician in vocational guidance, medical welfare in Nazi organizations, inspections of villages, all the preventive measures and the health pedigrees that have been partly planned and partly put in force all show the numerous and extraordinarily intensive demands made today by the state on the practice of the German physician. He receives more than ever before stimulation and general directions from headquarters. To his enlarged duties have been added enlarged rights and claims, such as leave of absence and compensation for sickness, rights which are administered by his own professional organization. These are clear signs that the medical profession is being made secure in public law.

That the measures which prohibited Jewish physicians with few exceptions from continuing practice after Oct. 1, 1938, would lead to a shortage of physicians could be foreseen. Emergency steps were taken. Official statements to the contrary, there is a shortage of physicians, for example in Berlin, where on Oct. 1, 1938, about 1,600 Jewish physicians were notified to cease practicing. The remaining Jews, in spite of their best intentions, are unable to give the great number of group patients the proper

attention. On the other hand, the fees charged private patients have been increased. There are said to be physicians who demand two and three times the fee formerly charged. In view of this serious situation, one hears occasionally the prophecy that the authorities will have no other choice than to recall the Jewish physicians. This seems improbable, if for no other reason than because the proponents of radical anti-Semitic measures are still powerful.

The few Jewish physicians who have been permitted to practice among Jewish patients may no longer call themselves physicians. A specialist in surgery, for example, must now designate himself as "Jewish specialist for surgery" (Jüdischer Fachbehandler für Chirurgie); in addition he must affix on each letterhead and prescription the stamp "Eligible to treat only Jews."

Another news item concerns hospital nuns. In one of the largest hospitals in Vienna notice was given to all such nuns, some of whom had been active for a few years and others for decades. Their places will be taken in the near future by members of the Nazi girls' clubs. As many girls as possible are speedily to learn nursing.

Medical Inspection and Health Passbooks

The regulations of mutual life insurance companies and the control of the health of adolescents require that an individual health passbook be kept by every one affected as well as by school children subject to medical school inspection. To unify these different functions, a royal decree has been signed authorizing a complete reorganization of the regulations. The school principal, the teacher and the nurse are to see to it that every one on entering is provided with a health passbook, which will be issued by the minister of the interior and public health and must be used by the person all his life. It may be set up, if the parents desire it, by a physician of their choice and at their expense. It is the property of the one whose name is inscribed and must be preserved by his family. The medical inspectors have a file which they keep and in which they note, besides the notations of the passbook, the instructions which they deem useful. For the records of the minister of the interior and public health they fill out blanks furnished by this department, and these remain confidential. Primary school inspectors and the teaching staff will be furnished by the medical inspector with the needful directions. This inspector will also furnish the pupil with useful instructions compatible with medical information of a confidential nature. Enough copies of the health passbook are furnished school principals by the minister of the interior and public health, on request and at the expense of community bureaus.

Insulin for the Treatment of Schizophrenia

H. Baonville, J. Ley, A. Titeca and J. Titeca made known before the Société de médecine mentale de Belgique the results of a year's insulin treatment of schizophrenic patients at the Neuropsychiatric Center of Brussels. The publication has aroused great medical interest because the results appear encouraging, and the experiment deserves to be continued. This study deals with fifty-four cases of schizophrenia in the hebephrenic, catatonic and paranoid forms treated daily for a period of three months from June 1937 to June 1938 by the insulin shock method, with the regular induction of a profound hypoglycemic coma. The cases in which the clinical picture showed cyclothymia or might be interpreted as a period of delirium secondary to mental degeneration or debility were rigorously excluded. The authors checked their diagnosis by a comparison with the proportion of patients with a diagnosis of schizophrenia, of whom annually a total of 400 are admitted to the clinic and have been treated there for at least two months during the preceding years.

The fifty-four cases are divided into three groups: (1) those in which the disease represented an evolution of less than one year (twenty-two cases), (2) those in which the disease indicated an evolution of from one to two years (fifteen cases) and (3) those representing more than two years (seventeen cases). The favorable results include complete clinical cure as well as improvement sufficient to permit the patient to return to normal life. The failures comprise slight or no improvement. There were seventeen favorable results and five failures in the first group, six favorable results and nine failures in the second and two favorable results and fifteen failures in the third. The best results were obtained in cases of paranoidism and hallucinations.

Lead Poisoning

In the session on studies of occupational diseases organized by the Union of French Metallurgic and Mining Industries, Dr. M. A. Langelez discussed the question of chronic poisoning in Belgium. Of 511 cases of occupational diseases observed in the last ten years, 369 were of lead poisoning. This condition, the author states, has undergone considerable modification for some years, both in its symptoms and in its evolution, because of our exact knowledge of the first indications, such as lead in the blood and urine, stippling in the erythrocytes, changes in the leukocytes, the lead line in the gums and nervous troubles. One can now avoid the serious consequences, particularly paralysis and encephalopathic disorders. Under certain circumstances, when ordinary means of prevention are clearly insufficient, utilization of the dangerous products must be prohibited. In Belgium, notably lead-containing enamels caused chronic lead poisoning.

Flemish Academy of Medicine

The *Belgian Monitor* has published a royal decree relative to the organization of a Flemish Academy of Medicine. Its purpose is, first of all, to answer, in cooperation with the Royal Academy of Belgium, questions submitted by the government and then to keep abreast with all the studies and researches that might contribute to the progress of medicine. The academy will consist of forty active members. The first fifteen will be chosen by the king and, in turn, elect the remaining. Also the academy will have the power to nominate honorary and corresponding members.

Marriages

FRANCIS CLIFFORD NESBIT, Atlanta, Ga., to Miss Anne Geraldine Nolan of Oklahoma City, in Decatur, Ga., April 12.

DOROTHY H. CHENEY, Newburyport, Mass., to Mr. Daniel Randolph Appleton of Kingston, February 25.

MAURICE EMANUEL SCHEETZ, La Fayette, Ohio, to Miss Alma Jones of Des Moines, Iowa, April 20.

JAMES CLARENCE GRIFFIN, Tampa, Fla., to Miss Mary Quinn Doke of Memphis, Tenn., April 24.

JAMES PAUL PROUDFIT, Washington, Pa., to Miss Jane Marie Sybert of Portage, April 15.

JAMES B. WALLER, Decatur, Ill., to Miss Esther Behnke of Whittemore, Iowa, in April.

FREDERICK CHRISTOPHER to Miss Dorothy Watt, both of Evanston, Ill., May 19.

SILVIO ERRICO to Miss Marguerite E. De Greve, both of Moline, Ill., May 4.

ANGELO LAPI, Canton, Ohio, to DR. K. RUTH MERRELL of Massillon, April 18.

HAROLD G. NIX to Miss Jean Gilmer, both of Tampa, Fla., April 15.

Deaths

Harry Elmer Peterman ⊕ Baltimore; Baltimore Medical College, 1895; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; ophthalmic and aural surgeon to the South Baltimore General Hospital; visiting ophthalmic and aural surgeon to the Maryland General Hospital; consulting ophthalmologist and otologist to the Frederick City (Okla.) Hospital; aged 67; died, February 25, of heart disease.

Cyrus Long Pershing, Denver; Columbia University College of Physicians and Surgeons, New York, 1908; associate member of the Colorado State Medical Society; formerly assistant professor of neurology at the University of Colorado School of Medicine; formerly superintendent of the State Home and Training School for Mental Defectives, Ridge, Colo.; served during the World War; aged 70; died, February 8, in the Fitzsimons General Hospital of coronary sclerosis.

Charles Fitzgerald, New Haven, Conn.; University of Vermont College of Medicine, Burlington, 1898; member of the Connecticut State Medical Society; veteran of the Spanish-American War; aged 62; on the staff of the Hospital of St. Raphael, where he died, February 9, of cerebral thrombosis, bronchopneumonia and hypostatic pneumonia.

James Robert Bolton, Beacon, N. Y.; University of the City of New York Medical Department, 1886; member of the Medical Society of the State of New York; on the staff of the Highland Hospital, Beacon, and on the advisory staff of the Vassar Brothers Hospital; aged 79; died, February 24, of valvular disease of the heart.

William Henry Hunsberger, Pennsburg, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; on the staffs of the Sacred Heart Hospital, Allentown, and the Jefferson Hospital, Philadelphia; aged 69; died, February 21, of coronary thrombosis and chronic myocarditis.

George Campbell Mizell ⊕ Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1901; at one time associate professor of physiology and gastrointestinal diseases at his alma mater; on the staff of St. Joseph Infirmary; aged 62; died, February 4, of acute cardiac decompensation, arteriosclerosis and chronic interstitial nephritis.

George H. Humphreys, Brockway, Pa.; College of Physicians and Surgeons, Baltimore, 1896; member of the Medical Society of the State of Pennsylvania; for many years president of the school board, and county coroner; aged 74; died, February 10, in the Elk County General Hospital, Ridgway, of carcinoma of the liver.

Frederick Dorr Carr ⊕ Batavia, N. Y.; University of Vermont College of Medicine, Burlington, 1908; for many years city bacteriologist and member of the board of health; medical director of the Genesee County Laboratory; aged 56; on the staff of the Batavia Hospital, where he died, February 12, of coronary embolism.

Thomas Woodburn Paton, Ypsilanti, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; member of the Michigan State Medical Society; on the staff of the Beyer Memorial Hospital; aged 67; died, February 10, in the University Hospital, Ann Arbor, of pneumonia and heart disease.

Edward Samuel Amsler ⊕ Rochester, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; aged 57; on the staffs of the Park Avenue Hospital and the Rochester General Hospital, where he died, February 5, of gangrene of the legs, coronary thrombosis and embolus in the abdominal aorta.

Abraham Louis Metz, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1893; professor emeritus of chemistry and toxicology at his alma mater; formerly city and state chemist; aged 75; died, February 10, in a hospital at Tucson, Ariz., of cardiac disease and bronchopneumonia.

Monroe Abraham Meyer ⊕ New York; Cornell University Medical College, New York, 1916; member of the American Psychoanalytic Association, American Psychiatric Association and the American Psychopathological Association; aged 46; was found dead, February 27, of self-inflicted stab wounds.

Asa Lee Pattee, Falmouth, Mass.; Eclectic Medical Institute, Cincinnati, 1895; formerly member of the board of health and state legislature; on the staff of the Barnstable County Sanatorium, Pocasset; aged 69; died, February 25, in St. Anthony's Hospital, St. Petersburg, Fla., of hypertensive heart disease.

Edwin C. M. Hall, New Haven, Conn.; New York Homeopathic Medical College, New York, 1883; at one time secretary of the Connecticut Homeopathic Medical Examining Board; on the staff of the Grace Hospital; aged 80; died, February 4, of myocarditis, endocarditis, nephritis and prostatitis.

Frederick Eft, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1892; member of the Medical Society of the State of Pennsylvania; formerly on the staffs of the Pennsylvania Hospital and St. Vincent's Hospital; aged 75; died, February 7, of cerebral hemorrhage.

Charles Edward Allison ⊕ Williamsport, Pa.; Jefferson Medical College of Philadelphia, 1899; past president of the Northumberland County Medical Society; served during the World War; president of the bank of Elysburg; aged 67; died, February 19, of carcinomatosis.

Ludwig Francis Lubeley, Denver; John A. Creighton Medical College, Omaha, 1910; member of the Colorado State Medical Society; aged 54; died, February 23, in St. Joseph's Hospital of gas gangrene of the right arm and shoulder, influenza and acute enterocolitis.

Clyde C. Phillips, Charlotte, N. C.; North Carolina Medical College, Charlotte, 1912; member of the American Roentgen Ray Society and the Radiological Society of North America; aged 48; was killed, February 11, when his shotgun was accidentally discharged.

Jean Sears Millard ⊕ Akron, Ohio; Harvard University Medical School, Boston, 1910; on the staff of the People's Hospital; medical director of the Goodyear Tire and Rubber Company; aged 62; died, February 24, in Phoenix, Ariz., of cerebral hemorrhage.

Charles Aloysius Coll ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1908; veteran of the Spanish-American and World wars; aged 63; died, February 23, in the United States Naval Hospital, of bronchopneumonia, heart disease and chronic cholecystitis.

Anne Walter Fearn, Shanghai, China; Woman's Medical College of Pennsylvania, Philadelphia, 1893; established a sanatorium bearing her name; author of "My Days of Strength"; aged 68; died, April 28, in Berkeley, Calif., of heart disease.

Marcus Beekman ⊕ Natchez, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1911; member of the Radiological Society of North America; on the staff of the Natchez Sanatorium; aged 54; died, April 23, of coronary disease.

George Christopher Gilfillen ⊕ Dayton, Ohio; Medical Department of the University of Cincinnati, 1912; fellow of the American College of Surgeons; on the staff of the Miami Valley Hospital; aged 50; died, February 22, of coronary occlusion.

Max Allan Dorland, Redondo Beach, Calif.; St. Louis College of Physicians and Surgeons, 1906; member of the elementary school board; on the staff of the Jared Sidney Torrance Memorial Hospital, Torrance; aged 58; died, February 18.

Samuel H. Hillin, Houston, Texas; Memphis (Tenn.) Hospital Medical College, 1890; aged 75; died, February 1, at the Memorial Hospital of pneumonia following a fracture of the hip.

John Bruce James, Richmond, Va.; Medical College of Virginia, Richmond, 1931; aged 33; died, February 6, in the Sheppard and Enoch Pratt Hospital, Towson, Md., of pneumonia.

Annie M. Mennie, Chicago; Illinois Medical College, Chicago, 1901; aged 72; died, February 11, in the Washington Boulevard Hospital, of carcinomatosis.

CORRECTION

Dr. Orcutt Not Dead.—The report of the death of Dr. Arthur Henry Orcutt of Oakland, Calif., in THE JOURNAL, May 6, 1939, page 1849, based on a newspaper clipping, was erroneous.

Correspondence

SULFANILAMIDE IN ACTINOMYCOSIS

To the Editor:—I should like to add corroboration to the results of Miller and Fell with sulfanilamide in actinomycosis (THE JOURNAL, February 25, p. 731).

On Feb. 12, 1937, I made a pathologic examination of two fallopian tubes and portions of two ovaries removed from a married woman aged 20. Smears and histologic sections indicated extensive actinomycotic infection. The operation was performed for nonspecific pelvic inflammation of six weeks' duration. It was an unsatisfactory operation owing to extensive adhesions and evident inflammatory activity. The pelvis showed gross evidence of infectious contamination. Convalescence was delayed and followed by a gradually increasing pelvic induration and mass formation associated with a low grade temperature. Potassium iodide and other medication were given without relief. High voltage roentgen therapy was suggested and refused. By this time the general condition of the patient was grave. On a purely empiric basis sulfanilamide was administered in regular, recognized, routine doses. The patient soon showed a surprising improvement, and the pelvic induration and mass slowly regressed and disappeared within eight months. Today the patient is without any evidence of her former infection.

W. E. B. HALL, M.D., Denver.
From St. Joseph's Hospital, St. Joseph, Mo.

USE OF SODIUM DIPHENYL HYDANTOINATE AS ANTICONVULSANT

To the Editor:—It is gratifying to see Dr. Kimball's report testifying to the effectiveness of sodium diphenyl hydantoinate as an anticonvulsant as used in his series of 152 cases since the beginning of 1938 (The Treatment of Epilepsy with Sodium Diphenyl Hydantoinate, THE JOURNAL, April 1, p. 1244).

His was the first clinic to which the drug was furnished after Dr. Merritt and I had given it a ten months trial under rigid precautions in our own wards. This in turn was only after we had demonstrated its ability to prevent experimentally produced convulsions and its low toxicity in animals (Putnam, T. J., and Merritt, H. H.: Experimental Determination of the Anticonvulsant Properties of Some Phenyl Derivatives, *Science* **85**:525 [May 28] 1937).

His observations are therefore of particular value. It is of course of great importance to record, as Dr. Kimball has done, any peculiar side effects which new drugs may produce. Dr. Merritt has in preparation a study of the toxic manifestations observed in a series of more than 300 cases for periods up to two years, which includes the phenomena, such as rashes, reported in our first clinical paper (Merritt, H. H., and Putnam, T. J.: Sodium Diphenyl Hydantoinate in the Treatment of Convulsive Disorders, THE JOURNAL, Sept. 17, 1938, p. 1068) some instances of the change in the gums, which Dr. Kimball so strikingly describes, and a few other miscellaneous disturbances.

While the incidence of hypertrophy of the gums has been lower in our series than in his—eleven out of 332 cases—(possibly because few of our patients were children), we do feel that the condition has only a superficial resemblance to scurvy, and in our cases there has been no evidence of a deficiency of ascorbic acid. Indeed, the case reported by Dr. Kimball might be taken as evidence against such a conception, since the hypertrophy of the gums persisted even after the level of ascorbic acid in the blood had been raised to a high normal. The hypertrophy of the gums does not cause the patient any inconvenience and can easily go unnoticed over long periods of time.

Dr. Kimball is in my opinion entirely justified in recommending that sodium diphenyl hydantoinate be given only under the direction of a physician. Medical supervision is of particular importance in severe cases, in which a compromise must often be made between the dosage required to prevent all attacks and that which produces no side effects. Encouragement and ingenuity must be employed more often in the use of sodium diphenyl hydantoinate than in the use of phenobarbital, but the results are usually worth while. Overdosage and individual intolerance are problems to which there is an obvious solution. As far as danger to life is concerned, the advantage appears to lie with sodium diphenyl hydantoinate, as compared to bromides and phenobarbital. It is difficult to give an animal enough sodium diphenyl hydantoinate by mouth to kill it, and no serious accidents have been reported from its use in the treatment of epilepsy, although some thousands of patients are taking it.

TRACY J. PUTNAM, M.D.
Harvard Medical School, Boston.

MAGNESIUM SULFATE IN PAROXYSMAL TACHYCARDIA

To the Editor:—In THE JOURNAL April 1 appeared a letter from Dr. L. Zwillinger of Prostějov, Czechoslovakia, relative to the therapeutic use of magnesium sulfate in paroxysmal tachycardia. I should like to correct a false impression which evidently was created by my informal discussion of Dr. George Fahr's paper. The mere fact as stated that I had successfully used magnesium sulfate in several cases should not have been construed as a claim to priority in its use. In Europe as well as in the United States through THE JOURNAL the work of Dr. Zwillinger has been publicized. An editorial "we in Vienna" might have been in better taste, or since the purpose of my brief discussion was merely to remind the audience of the use of magnesium sulfate in tachycardia, the "first person" could and should have been omitted entirely. I am but one of a number of cardiologists who used the drug in Vienna.

WILLIAM DRESSLER, M.D., New York.

EXPERIMENTAL RENAL ATROPHY

To the Editor:—In an editorial (THE JOURNAL, April 8, p. 1344) on the recent work of Drury (*J. Exper. Med.* **68**:693 [Nov.] 1938) entitled "Experimental Renal Atrophy," which deals with experimental renal insufficiency and hypertension in the rabbit, several statements are made which are misleading. The writer of the editorial states that the application of our clamp (Goldblatt, Harry; Lynch, James; Hanzal, R. F., and Summerville, W. W.: *J. Exper. Med.* **59**:347 [March] 1934) to the main renal artery, like other technics employed for the purpose of producing experimental hypertension, produces necrosis or other pathologic changes in the kidney tissue, particularly in rabbits. Although it is true that necrosis can be produced at will by our method by excessive constriction of the main renal arteries and that this is more likely to occur in small animals, yet it is equally true, and of the greatest importance, that by our method hypertension can and has been produced in the dog, monkey, rabbit and rat by ourselves and many other investigators without the complication of renal necrosis (Goldblatt, Harry: Harvey Lectures, 1937-1938, p. 237). What is even more important is that by our method hypertension has been produced, without demonstrable renal excretory insufficiency, a complication which it is evidently difficult to avoid by the method of Drury. In fact, this method was first described by Drury in 1932 (*Proc. Soc. Exper. Biol.*

& *Med.* **29**:856 [April] 1932) for the production of renal insufficiency, and it is only recently that he found that elevation of blood pressure also results. It is undoubtedly valuable for this purpose in small animals, and it is especially useful if it is desired to study accompanying renal excretory insufficiency. The method of Drury is not a basically new one for the production of the hypertension, but it is a different method for the production in small animals of the renal ischemia that induces the hypertension. By this method Drury has so far been able to verify our finding that unilateral as well as bilateral renal ischemia may cause elevated blood pressure and also has confirmed some of the other results obtained by ourselves and others who have used our method of constricting the main renal artery. The important fact is that renal ischemia initiates the hypertension. New methods of producing renal ischemia in small animals, or for other special purposes, are valuable, and in this respect Dr. Drury's contribution is of great importance to investigators of the causative relation between kidney and hypertension. Incidentally, the title of the editorial, "Experimental Renal Atrophy," should have been "Experimental Renal Hypogenesia," since Drury's method is designed not so much to cause reduction in the size of the adult kidney but to prevent the full development of the young kidney.

HARRY GOLDBLATT, M.D., Cleveland.

"COMPLICATIONS DUE TO ARSENICAL THERAPY IN SYPHILITIC PREGNANT WOMEN"

To the Editor:—In THE JOURNAL, April 22, appears an exceedingly valuable contribution on the complications due to arsenical therapy in syphilitic pregnant women, with a report of seven maternal deaths, by Dr. Norman R. Ingraham Jr. Two of the fatalities (cases 3 and 4) were designated as acute circulatory collapse: one following the third injection of neoarsphenamine and the other following a second injection. Each death occurred within an hour after treatment. In commenting on the series, Dr. Ingraham notes that "81 per cent of these fatal treatment reactions were precipitated by three or less arsenical injections" and that "death likewise has been a matter usually of only hours or days."

It is apparently obvious to the author that the fatalities cannot be due to the heavy metal, for he goes on to discuss "the possibility of atopic drug allergy" or "sensitization (acquired allergy)" and states that "such speculation finds further confirmation in the pathologic observations . . . consisting only of extreme peripheral congestion of acute circulatory collapse, with the hemorrhagic phenomena in the brain and other organs." Later Dr. Ingraham uses the phrase "colloidoclastic shock" for these conditions.

I should like to call to Dr. Ingraham's attention the laboratory and clinical description of "speed shock," which I published in the *Archives of Internal Medicine* (**47**:259 [Feb.] 1931), and in THE JOURNAL, March 16, 1935, page 878. There will be found a description of the type of circulatory collapse described in these cases. The observations made on experimental animals closely parallel the autopsies in human beings. The discussion of the possible relationship of "speed shock" to nitritoid crises and to anaphylactoid and colloidoclastic reactions indicates clearly that these may all be identical.

The importance of the recognition of the syndrome of "speed shock" lies in the fact that a mechanism, otherwise mysterious, becomes quite patent and that the prophylactic therapy of the slow intravenous drip will prevent not only the fatalities associated with "speed shock" but also the minor acute disturbances such as nitritoid crises.

HAROLD THOMAS HYMAN, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DAILY WATER REQUIREMENTS

To the Editor:—Many physicians and school nurses teach that all persons should drink from six to eight glasses of water a day between meals, and especially is this important if a person suffers from constipation. Some, however, caution against overindulgence in salt because it increases thirst and the consequent drinking of water overtaxes the kidneys. The drinking of plain water is to many persons decidedly diuretic, yet the addition of from one-fourth to one-third teaspoonful of salt per glass causes it to be eliminated by way of the intestine instead. Is forced drinking of water without thirst desirable? The majority of people are interested in hygiene these days but advising them becomes difficult with changing concepts and professional disagreements.

M.D., California.

ANSWER.—It is unfortunate that medical "authorities" do not seem to agree on the simple proposition of the daily water requirement of normal persons. Ordinarily the sensation of thirst is an adequate guide to the amount of water required by the body, because it is conditioned largely by the intake of sodium chloride. Therefore, forced drinking of water is not indicated unless there is fever, an infection of the urinary tract or a suppression of the sense of thirst by various causes, including a low salt diet. Under normal conditions a fluid intake of 2½ or 3 quarts a day, including all beverages, is adequate except in very warm weather. There is, of course, no harm in drinking somewhat more, provided the circulation is normal, the prostate is not hypertrophied and sleep is not disturbed by nocturia. In the presence of epilepsy, hypertension or other potential heart disease, nephritis, toxemias of pregnancy and other conditions in which a high salt and fluid intake may do considerable harm, the physician should fit his advice to the individual patient's needs.

CELIAC DISEASE

To the Editor:—I would appreciate a discussion of the etiology, diagnosis, prognosis and treatment of celiac disease (chronic intestinal starch indigestion) in a child 23 months old. Please also give references.

M.D., New Jersey.

ANSWER.—When celiac disease occurs in children who have always been carefully supervised, it is convenient to presuppose the factor of congenital weakness. There is apparently a faulty digestion of fat or, more probably, difficulty in the absorption of fat, although this is not universally admitted. The pathogenesis is not clear. Some clinicians consider celiac disease to be the infantile form of sprue, both tropical and nontropical. These relationships, however, are not completely established.

The disease usually begins after 6 months of age, most frequently in the last quarter of the first year or in the first half of the second year. The stools are usually bulky, light gray or nearly white, often formed, but at times diarrheal. The number of stools is increased and they contain an excessive amount of fat. As the disease proceeds, the nutrition suffers. Nutritional impairment is further shown by the slow body growth. The abdomen is enlarged owing to dilatation of the colon.

Recovery is slow even under treatment, the disease often lasting for years. In mild cases more rapid improvement can be expected. There is a tendency to acute exacerbation at irregular and often frequent intervals. Between attacks the evidences of indigestion may at first be slight or even wholly absent, but it is not long before there is an increase in the intensity of the symptoms until some of them are constantly present. The prognosis under treatment is, on the whole, good except in the instances in which little can be found wrong with the hygiene and diet and there seems to be a constitutional or an early acquired and persistent lack of functional intestinal power. In such cases death from exhaustion is liable finally to occur. There is always too the danger that the impaired general health may diminish the power of resistance to some intercurrent disorder. The general condition of patients who recover may improve long before the excessive fat disappears from the stools. Complete recovery in some cases includes an ability to carry on normal digestion to all intents and purposes, although in others a tendency to an easily upset intestinal tract persists throughout life.

The essential factor in the treatment of celiac disease is dietary regulation. In celiac disease much loss of calcium occurs, and

hence the administration of a considerable amount is indicated. This may be accomplished through the ingestion of casein or by the addition of calcium gluconate to the diet. When diarrhea is present, vitamin C is poorly absorbed. Vitamins A, D and C may be taken in liberal quantities, A and D through cod liver oil concentrates or in the form of carotene and viosterol, and the necessary quantities of C in the form of orange juice and tomato juice, which are well tolerated.

Protein milk may form the basis of the diet. This can be given in a quantity equivalent to one packed level tablespoonful per pound of body weight. The dried protein milk for the day's feedings is mixed with about a quart of warm water and the mixture is passed through a fine sieve several times. The total amount is divided into four feedings, which are given during the day with a long night interval. A small amount of saccharin may be added to improve the flavor. The amount of protein milk is gradually increased until the infant is receiving as much as one tablespoonful of the dried powder per pound of expected body weight for the age, according to the plan of treatment recommended by Sauer. This forms the sole diet for three or four weeks, or until the stools have become firm and the child begins to gain weight.

The next addition to the diet consists of boiled whole milk, equal parts of evaporated milk and water or whole lactic acid milk, which takes the place of the protein milk, the skimmed milk or the fat-free buttermilk which have up to this time formed the basis of the diet.

Well cooked and strained vegetable purées are begun in small amounts and gradually increased, and two whole eggs may be given in a day. These should be soft boiled or coddled. This diet is continued for a period of several months, usually four or five.

The next addition consists of carbohydrates—at first a very small amount of well toasted bread or zwieback and later cooked cereals, such as corn flakes, grape-nuts, puffed wheat or rice. These are served with skimmed milk but without sugar or cream. If starch in this form is tolerated, the amounts are increased and later well cooked rice is added. Corn syrup may be substituted for the dextrose at this stage.

In the treatment of any case of celiac disease it is essential that proper attention be paid to the general hygienic surroundings of the child. Fresh air, sunlight, proper clothing and sufficient rest all tend to promote recovery. These children are difficult to handle, fretful and querulous. Whoever cares for them should be even tempered, considerate and possessed of infinite patience. The diet must be persisted in and no variations made merely for the purpose of satisfying the child. With proper treatment patients with celiac disease may reach approximately normal physical and mental development.

TREATMENT OF VAGINAL BURN

To the Editor:—Kindly advise the best method of treatment for a vaginal burn which was done with an air spaced pyrex tube, short wave vaginal electrode, area about 2 by 2½ inches. The patient has been getting tampons twice a week and a cleansing douche every day or every other day. Before the tampon was applied, 5 per cent silver nitrate was used.

M.D., Michigan.

ANSWER.—A speculum should be inserted into the vagina but with great gentleness and care to expose the burned area. Then a greasy substance should be applied all over the entire burned area and a loose pack inserted to prevent apposition of the vaginal walls and subsequent adhesions. The simplest way to accomplish this is to insert gauze thoroughly saturated with sterile petrolatum or hydrous wool fat into the vagina. The petrolatum gauze should be removed every day and the vagina gently cleaned of any débris and another pack replaced in the vagina. As soon as the risk of adhesions seems to be passed, only petrolatum should be applied but no pack. Then even this may be discontinued. However, repeated examinations should be made to make certain that there will be no contraction of the vagina as a result of the scar tissue which will form after the burn has healed completely. If shrinking of the vagina does occur, glass dilators will have to be used to prevent constriction. The patient can be shown how to insert these glass dilators herself.

PROTAMINE ZINC INSULIN, DIABETES AND HERPES ZOSTER

To the Editor:—I should like to know whether my experience with protamine zinc insulin has been duplicated by others. Both in private practice and in clinics with a total diabetic population of about 1,500 I have noticed that herpes zoster has been an extremely rare complication of diabetes. We have had only two cases in more than ten years. Joslin, in his book, lists seven cases in a total of some 6,000 diabetic patients. Since the use of protamine zinc insulin, however, we have had at least a dozen cases of herpes zoster among our patients. Taking into consideration the comparatively short time that the newer insulin has been used, this represents a great increase in the incidence of the complication. I am wondering whether the explanation lies in the fact that the protamine, being a protein, cannot be sterilized by heat and that passage through a Berkefeld filter would permit the virus of herpes zoster to be carried into the final preparation.

E. M. Abrahamson, M.D., Brooklyn.

ANSWER.—Herpes zoster not infrequently occurs in the course of diabetes and is far more common than might be inferred from the reference cited. Despite extensive use of protamine zinc insulin no increase in the incidence of herpes considered attributable to the insulin has been noted in a large experience. Whether it is more frequent in diabetic than in nondiabetic persons is an open question. It may seem to be more frequent now, because diabetic patients are living longer and are watched more closely by their physicians, and all complications are more accurately recorded. Herpes zoster is in general more frequent in older than in younger persons; diabetes originates in at least two thirds of the cases after the age of 40.

CEREBROSPASTIC DIPLEGIA AND SPEECH TRAINING

To the Editor:—A girl aged 4 years had a cerebral hemorrhage at birth. The lesion was definitely diagnosed by x-ray examination following injection of air into the ventricles. She has a definite Little's disease syndrome but began walking at about 30 months. The lesion seems to be located over the speech center, as she does not talk. She will obey commands and shows mentality otherwise of about a 2 year old child. She had pneumonia at about 9 months of age. Following the febrile stage she made definite improvement. Hence the family feels that fever therapy might do good in spite of the diagnosis that has been made. Is there any literature you might have to offer on therapy or do you suggest a school of speech?

M.D., Illinois.

ANSWER.—As far as can be ascertained, the literature offers no definite proof that fever therapy will ameliorate or aid in the treatment of Little's disease (cerebrospastic diplegia). A special school where attention can be given to speech training and physical therapy for the development and coordination of muscles would be advisable for such a child.

DESTRUCTION OF ENTIRE NASAL SEPTUM

To the Editor:—A woman aged 43 presents a nasal condition the cau and cure of which baffle me. The history dates back twenty-nine years. that time there was a small "scab," as she describes it, on the left side the septum of the nose; following this there was a small perforation the septum. This gradually increased until at present the entire septu is destroyed; the perpendicular plate of the ethmoid is eroded. Hemorrha is frequent, at other times just a serous discharge. The turbinates becor congested. Severe headaches result until free drainage is established the nose. The Wassermann test is consistently negative. The nasal bo is not involved. No metastasis or polypi are present in the nasopharynx there is no adenopathy of the glands in the neck. X-ray examination the sinuses shows slight cloudiness. Smears show no organisms. T patient's father died at the age of 75 of chronic fibroid pulmonary tube culosis. He was said to have had tuberculosis cutis. Treatment has co sisted of nose drops, cauterization (with phenol, silver nitrate, and so or and roentgen treatment, with no improvement. Specialists as well general men have treated the patient and have failed to make a diagnosi Please outline the cause and cure.

M.D., Kansas.

ANSWER.—A spontaneous ulceration of the septum beginnin in the cartilaginous portion leading to a perforation which slowl becomes larger and larger can be due only to some specific origin which is not malignant. A simple traumatic perforation neve extends beyond the cartilage unless there is a general atrophi rhinitis. The case described was most likely a lupus, whic presents its characteristic appearance only in the early stages After the septum has been perforated the characteristic appl jelly nodules are more difficult to isolate and observe. It i rare, however, for a lupus of the septum to be unaccompanie by lesions elsewhere in the nasal cavity or in the skin. How ever, it is not impossible. A biopsy taken from the margin o the perforation might still show the typical granuloma with giant cells. The only treatment that offers a chance of arrest ing the process is destruction of the margins with diathermy or the local use of radium. A total of from 400 to 600 mg. hours may safely be used if adequately screened.

Since there is no mention of scabbing or thick secretion, there would be no indication to use any local medication except for occasional introduction of petrolatum.

DIABETES AND GOAT'S MILK

To the Editor:—Several patients with diabetes have been on insulin and have had more or less difficulty, probably because of the inaccuracies of diet or measuring of the insulin dose. Many of these patients have been led by their friends to begin drinking goat's milk and to my great surprise have been able to lower the insulin dosage and finally abandon it altogether and still continue to be sugar free. I have always held that goat's milk was no different than cow's milk except the minor difference in the mineral content and the slight difference in the protein. I can see no reason why goat's milk should be of value. After having seen many of these patients improve without any other change in diet, I feel that there must be some value in it. Have there been any well controlled experiments which would throw any light on the subject?

M.D., New York.

ANSWER.—There is nothing in the chemical composition of goat's milk as compared to that of cow's milk to suggest that the former might be of value in the treatment of diabetes. According to Bosworth and Van Slyke (*J. Biol. Chem.* **24**:173 [March] 1916), its average food value and salt content compare with cow's milk as follows:

	Cow's Milk	Goat's Milk
Percentage of fat	3.90	3.80
Percentage of milk sugar	4.90	4.50
Percentage of protein	3.20	3.10
Percentage of salts	0.910	0.939

Other analyses give slightly different figures.

The analysis of the casein does not differ greatly from that of the casein of cow's milk. There are minor differences in the distribution of phosphates and in the chloride content. It is perhaps of interest, because of recent knowledge of the association of zinc and insulin, to note that Koga (*Keijo J. Med.* **5**:106 [June 30] 1934) found that the zinc content of cow's and goat's milk is approximately the same.

Metabolic studies have been reported only on nondiabetic infants. Sherman and Lohnes (bulletin 429, New York Agricultural Experimental Station, Geneva) found no definite difference in the rate of gain of infants fed cow's and goat's milk. Daniels and Stearns (*Am. J. Dis. Child.* **30**:359 [Sept.] 1925) found that normal infants retained less nitrogen (from 17 to 25 per cent in one series, and from 42 to 44 per cent in another) on a diet of goat's milk than on one of cow's milk.

It would be necessary to have better controlled observations of the cases of diabetes in question, so as to eliminate numerous other possible factors in the improvement, before it could be concluded that the goat's milk was of any positive therapeutic value. It seems extremely unlikely that the use of goat's milk without any other change in diet could have been solely responsible for the changes noted. One is reminded of the old Donkin "milk cure" for diabetes in which milk supplanted all other articles of diet, thus providing an intake of food which was comparable to some of the present day high carbohydrate diets.

ANHIDROTIC HEREDITARY ECTODERMAL DYSPLASIA

To the Editor:—Is there any therapy for a familial absence of sweat glands as shown by inability to perspire and distress when the temperature is raised?

J. R. DUNDON, M.D., Milwaukee.

ANSWER.—Hereditary ectodermal dysplasia of the anhidrotic type is a rare anomaly and all cases should be studied and reported. It appears in male children as a rule and is transmitted only by the female. There are a few exceptions to this rule, such as the case reported by Goeckerman (Congenital Ectodermal Defect, *Arch. Dermat. & Syph.* **1**:396 [April] 1920) and the cases recently reported by Kerley (Hereditary Ectodermal Dysplasia, Non-Sex Linked Type, *Arch. Pediat.* **55**:211 [April] 1938). In all the cases there have been other ectodermal defects, such as deficiency of hair and teeth, a peculiar depression of the bridge of the nose, mistakenly called a saddle nose, bulging of the forehead, even deficiency of the adrenal cortex as noted by Thannhauser (Hereditary Ectodermal Dysplasia of the Anhidrotic Type, THE JOURNAL, March 14, 1936, p. 908). The first case of this kind was reported by an American dentist (Guilford, H. S.: A Dental Anomaly, *Dental Cosmos* **25**:113, 1883).

Under moderate temperatures these patients are comfortable, for insensible perspiration, so called, is not dependent on the action of the sweat glands, as Loewy has shown. His patients with the ectodermal defect eliminated as much water as those with normal skin. Only when the temperature is high, calling for real sweating to keep down the body temperature, do they suffer. Air cooled rooms in which the patient can remain when the weather is hot solve the problem for those able to afford it. Keeping the underwear wet may also be tried. Anointing the skin frequently with a water-containing ointment may be of service. The following may be tried: wool fat 1 Gm., petrolatum 2 cc. and rose water 3 cc.

Mayr (Handbuch der Haut- und Geschlechtskrankheiten, Berlin, Julius Springer, 1932, vol. 13, pt. 1, p. 26) suggests trying pilocarpine from 5 to 15 mg. (one-tenth to one-fourth grain) in an effort to stimulate whatever sweat glands there may be. This, if tried, must be done with caution, for the action of pilocarpine varies greatly in different individuals.

COUCHING A CATARACT

To the Editor:—In Isabella of Spain; the Last Crusader (1451-1504) William T. Walsh on pages 56-57 states: "Jewish physician and astrologer had just restored the sight of one of the King's eyes by couching (King Juan of Aragon). Juan urged the Jew to heal the other eye. The doctor pleaded that the planets were unfavorable. Juan threatened him with death, but the Jew refused to operate until October, when he couched the other eye with complete success. Juan restored to sight at 80, put on his armor." Webster's Dictionary says "Couch (surgery): Formerly, to treat (a cataract) by turning down or displacing the opaque lens of the eye." In what history of medicine is this old procedure mentioned?

I. H. KIESLING, M.D., Nashwauk, Minn.

ANSWER.—The couching of a cataract is an old procedure. It is mentioned at greater or less length in practically all histories of medicine that deal with ophthalmology. Apparently couching originated in India, where it is still practiced by the natives (Hirschberg, Julius: Ueber den Star-Stich der Inder, translated by Surg. Capt. Maynard, *Indian M. Gaz.*, No. 6, June 1894). It did not appear to be known to the Greeks, and the first mention is by Celsus in the time of Nero. It was of course known to the Arabians, but no mention of the method appears in the old Egyptian literature (The Tadhkirat of Ali ibn Isa of Baghdad: Memorandum Book of a Tenth Century Oculist, translated by Casey A. Wood, page 81). A complete description of the history of couching by Julius Hirschberg (The History of Ophthalmology) appears in Graefe-Saemisch Handbuch der gesamten Augenheilkunde, second edition, volume 12, chapter 13, page 35. Descriptions of the methods of couching can be found in The American Encyclopedia of Ophthalmology, vol. 2, page 1473, and vol. 5, page 3544.

ACNE ROSACEA

To the Editor:—A white man aged 60 has been troubled for years with acne rosacea of the nose. He has consulted many physicians and on two previous occasions, five years ago and three years ago, took x-ray treatments for this condition. In October I gave him three treatments followed by apparent recovery, but the tendency toward the formation of brown scabs is now returning. I have told the patient that this is a chronic type of disease in which x-rays are helpful as a method of treatment, but the possibility of permanent cure is not good. I would appreciate your opinion as to the value of x-rays in acne rosacea; also I should like to know whether or not there is any treatment that will produce a permanent cure.

M.D., Iowa.

ANSWER.—The use of x-rays is one of the most valuable methods for the local treatment of acne rosacea. They by no means effect a permanent cure in all cases, though they are helpful in the majority. Care should be used not to give too large doses or to continue their use too long. There is no method known which would promise a permanent cure. The disease can be ameliorated and more often cured at its outset. Astringents, such as the much used lotio alba, may be sufficient to accomplish this if continued for a long time. Better results may be expected if general measures are combined with local measures. Highly spiced and hot foods and drinks as well as alcohol must be omitted. Anything that irritates the skin, such as wind and weather and strong soaps, should be avoided.

MALARIA IN PREGNANCY

To the Editor:—What is the advisability of permitting a pregnancy to continue in a patient who has had tertian malaria during the past fall. At the present time the patient shows no ill effects from the disease and is still taking regular quinine treatments every month. She has had no recurrences, but her daughter has.

M.D., Michigan.

ANSWER.—There is no indication to terminate pregnancy in this case; malaria does not affect the child unless the disease is acute and severe or unless malarial cachexia develops. Since pregnancy, labor and the puerperium favor relapses, it would be wise to continue prophylactic treatment for the first six months. The dosage should not be large—about 10 to 15 grains (0.65 to 1 Gm.) a week, preferably divided. Recent experiments have shown that even a normal dose of quinine may produce changes in the auditory nerve resulting in deafness (West, R. A.: *Am. J. Obst. & Gynec.* **36**:241 [Aug.] 1938), and there is some ground for believing that large doses in man may do the same. More clinical research on this matter is needed, but it is worth keeping in mind.

LESION OF SPINAL CORD

To the Editor:—A white man aged 38, a superintendent of schools, consulted me for tachycardia of from 90 to 100 and overweight (213 pounds [96.6 Kg.], 6 feet 2 inches [188 cm.]). The blood pressure was 135 systolic, 75 diastolic. There was no evidence of sclerosis of the arteries by palpation. (He had no complaint of any ailment and came only because of membership in the army reserves). After four weeks of treatment, which consisted of a controlled low calory diet and 5 drops of 50 per cent solution of potassium iodide three times a day, he weighed 200 pounds (91 Kg.), the blood pressure was 115 systolic, 75 diastolic, and the pulse 75. Three weeks later he began noting slight weakness of the legs, which was relieved by rest. About 1 p. m. (after attending a dance the previous evening after a strenuous day in the city) his lower limbs became suddenly paralyzed and he sank to the ground in his garage. He called for help and was carried into the living room. Examination within half an hour revealed a blood pressure of 115 systolic, 70 diastolic, a pulse of 78 and a temperature of 98.4 F. He was lying down and unable to move from the hips down. The pupils were equal and regular and reacted to light. The abdominal responses were normal, the knee jerks were equal and slightly hyperactive, the plantar response was not present and the Gordon, Oppenheim and Chaddock reflexes were also absent on both sides. There was no ankle clonus. In the next twenty or thirty minutes movement returned to the right foot. He was then moved to a bed and warm blankets were applied, whereupon he stated that he was unable to feel the warmth with the left leg from the knee down. A check-up of the cranial nerves revealed all to be intact. (Nystagmus was not present.) The biceps and triceps reflexes were normally present on both sides. The Hoffmann response of the thumb could not be elicited. A normal plantar response now occurred on the right, which foot and leg he moved with ease and normally. Pain sensation (with pinprick) was normally present except from the knee down on the left leg. Six hours after the occurrence of paralysis there was a prickly sensation of the skin of the left leg which lasted for half an hour. Soon thereafter he was examined. He was then able to move his left foot and knee but some weakness remained at the hip. Plantar response was now present and normal and equal to that of the right. Other reflexes were unchanged. Examination of the blood and urine gave negative results: hemoglobin content 85 per cent, red cells 5,100,000, white cells 5,800, polymorphonuclear leukocytes 60 per cent; specific gravity of the urine 1.018, albumin and sugar not present and only a few epithelial cells found on microscopic examination. A blood Wassermann test has been taken as a routine every two years since 1926 and has always been negative. There was complete return of strength in the ensuing few days and the remainder of the Christmas vacation he spent on a 1,200 mile automobile trip with his family. At present, three weeks after the attack of paralysis, he feels entirely normal and is doing his regular work. There is no history of any such occurrence in any member of his family. I shall appreciate your suggestion for further examination and also as to what diagnosis or possible diagnoses may be applied. What is the prognosis?

M.D., California.

ANSWER.—The patient has, of course, a lesion of some kind affecting the spinal cord. The two common conditions that must be considered are a tumor of the spinal cord and multiple sclerosis. As long as his condition remains normal it would be better to do nothing. If symptoms return an injection of iodized oil into the cisterna magna will tell whether or not it is a tumor and, if a tumor, where it is located. If the iodized oil descends to the bottom of the canal there is almost positive evidence that no tumor exists, and the probable diagnosis is multiple sclerosis. The prognosis, of course, depends on the character of the lesion.

THYROID AND PERMANENT WAVE

To the Editor:—Would the administration of thyroid extract to a patient over a considerable period have any effect on the patient's hair from the standpoint of its response to permanent waves? Three patients have told me that within a month or two after starting such medication their beauty operators asked them if they were taking thyroid because of the fact that the permanent waves were not taking the way they had before. I would be most happy to know if any work has been done or any observations made on this problem.

RICHARD B. SCHUTZ, M.D., Kansas City, Mo.

ANSWER.—*Hyperthyroidism may cause* premature graying of the hair, especially over the temples and above the ears. The hair of the whole body becomes thinned, not sparing the eyebrows and lashes or the scalp. The skin is usually moist, sometimes with pigmentary changes such as vitiligo or a generalized darkening.

Myxedema, the hypothyroidism of adults, produces in 90 per cent of cases a dry skin with dry and harsh hair, and an alopecia. If a patient in this condition is getting insufficient thyroid medication, one might expect some difficulty with the curling process. This does not apply in the cases cited in the query. In patients on treatment with thyroid extract it is not to be supposed that a hyperthyroid condition can exist. If thyroid medication is indicated, one would naturally expect the condition of the hair to be improved, being restored to a more nearly normal state.

So far as recent medical literature shows, there has been no research tending to give a scientific basis for the theory that small amounts of thyroid extract given a patient who is in need of such treatment can exert any deterrent effect on the susceptibility of the hair to the action of alkalis or heat. Until such work has been done and substantiated, the theory must be considered untenable. It is difficult to avoid the suspicion that this is just another excuse for a failure to produce a satisfactory wave, a failure really due to imperfect technic.

GRANULOMATOUS ULCER ON FLOOR OF NOSTRIL

To the Editor:—A man aged 31 has had an ulcer on the floor of the left nostril the size of a dime (18 mm.) for eight months. The diagnosis, based on microscopic examination of material obtained at biopsy, is chronic granuloma consistent with tuberculosis or sarcoid. What treatment would you advise? There is no evidence of tuberculosis in any system and the Wassermann reaction is negative.

M.D., Massachusetts.

ANSWER.—If the diagnosis is well established energetic and persistent local treatment is indicated. The treatment of choice perhaps is the use of the galvanocautery, a fine point being introduced repeatedly into the ulcerated area and also about the margins to induce a limiting fibrosis. This may be used directly on the ulcer at first or after extensive curettement. Diathermy may also be used to destroy the diseased tissue; or chromic acid may be used if the former two methods are not available. Cauterization may be repeated every ten to twenty days, and in the intervals the patient should have some ointment to apply locally in order to keep crusts from forming.

Applications of radium with a dosage of from 100 to 200 milligram hours applied directly to the lesion have given satisfactory results. Roentgen therapy and electrolysis have not given as good results as the other treatments described. It is needless to say that despite the lack of evidence of systemic tuberculosis general hygienic and supportive measures should be advised.

CONTINUED POSTOPERATIVE PELVIC PAINS

To the Editor:—I am seeking information regarding those patients who have persistent postoperative pains following pelvic operations. Fortunately they are not common. I have patients who had surgery done over two years ago and still continue to have pains in the pelvic regions and pains referred to the back and down the thighs. They have had general supportive or tonic and vitamin therapy and various forms of local therapy such as diathermy, tampons, douches and enemas, but to no avail. Can any one suggest a remedy for these cases?

M.D., Illinois.

ANSWER.—Although it is unfair to state that there is always a demonstrable cause sufficient to explain cases of persistent pain, most of these patients have adhesions, inflammatory masses, or dragging organs with a disturbance of function.

Helpful factors in surgical technic which merit emphasis include the employment of rubber packs to wall off the bowel, deliberate technic in contrast with haste, and placement of the pelvic organs and tissues so that they are well supported but, above all, so that they are free from undue tension.

In those instances in which no pathologic change is demonstrable, frequent causes of discomfort include constipation; improper diet, particularly overeating and hasty eating, also indulgence in too much candy and pastry and too many coarse vegetables, raw fruits and salads; alcohol, a common cause of "colitis"; excessive coffee; lack of sufficient walking and other activities outdoors; personal maladjustments or unhappiness, often accentuated by too much bridge and employment of time with occupations which disturb rather than add to one's poise.

Elliott treatments, sun baths, hydrotherapy, change of climate, sedatives, thyroid therapy and vitamins (with emphasis on liver preparations) are among the items in specific therapy which merit particular mention.

CONGENITAL UMBILICAL HERNIA

To the Editor:—On December 14 I delivered a child with a large hernia into the umbilical cord. This hernia contained the liver and part of the stomach and transverse colon. Its wall consisted of only peritoneum and the amnion of the cord. Immediate surgical repair was done and the infant has survived. I find but little reference to this condition in recent textbooks on obstetrics and pediatrics. What is the incidence and mortality of this condition?

J. H. HOSKINS, M.D., Wahpeton, N. D.

ANSWER.—According to H. B. Saunders (Surgical Treatment of Congenital Umbilical Hernia, *Illinois M. J.* **51**:204 [March] 1937), true congenital umbilical hernia occurs about once in 5,000 deliveries, and such a hernia containing intestine or other abdominal contents occurs about once in 10,000 cases. In an excellent summary of the literature of this anomaly, Julius Jarcho (Congenital Hernia with a Report of a Case Involving the Liver, *Surg., Gynec. & Obst.* **65**:593 [Nov.] 1937) states that in 109 tabulated cases of congenital umbilical hernia the liver was present in thirty-one instances. About 1930 a number of articles

appeared in the literature, most of the authors reporting a single case. The mortality, as might be expected, is high, owing to four definite factors: 1. The effect of anesthesia on a premature or newborn infant. (There is no general agreement as to whether a local anesthetic is safer than ether.) 2. The result of shock and as a direct result of manipulation and operation. 3. General peritonitis. The resistance of the newborn to infection is extremely low, and any method which will reduce this factor should be the one of choice. Horwitz (Hernia of Umbilical Cord: Exomphalos, *Ann. Surg.* **92**:454 [Sept.] 1930) suggests extraperitoneal closure. 4. The inability to return the liver or extra-abdominal hernial contents to the abdominal cavity. Of course, when this is mechanically impossible death ensues within a short time.

BASAL METABOLISM IN CHILDREN

To the Editor:—Since patients in the department of basal metabolism are mainly children, we often encounter cases in which we are at a loss to determine the normal values for the patient. The medical literature is full of controversy regarding the best way to predict normals in infants and children. May I therefore have recourse to your wide experience to tell me which is the best formula for predicting normals. The Aub-Du Bois and Harris-Benedict formulas are intended. I would be much interested to know also what kind of apparatus (with a complete description) you would use in taking the basal metabolic rates of infants and children.

N. R. BOUZIANE, M.D., Montreal, Canada.

ANSWER.—The determination and interpretation of the basal metabolism of infants and children differs principally from that of the adult in that during the former period there is rapid growth and change in the body, while in the latter the body has become standardized. When one considers the period of childhood a distinct division must be made at the age when it is possible to obtain the basal metabolism accurately, collecting the breathing air through a mouthpiece with the help of a nose clip. This requires the intelligent cooperation of the child, and except in rare instances basal periods cannot be obtained with the so-called portable apparatus under the age of 7 years, and the physician should not depend on observations obtained at earlier ages by this method. The metabolism of children younger than 7 years has been obtained in cot chambers which are usually constructed in two sizes, one for infants up to 2 years and the other capable of holding children from 2 to 12 years. The earliest one used in children for relatively short periods was described by Benedict and Talbot ("The Gaseous Metabolism of Infants," publication 201 of the Carnegie Institution of Washington, 1914; and Some Fundamental Principles in Studying Infant Metabolism, *Am. J. Dis. Child.* **4**:129 [Sept.] 1912). This was a closed circuit. Subsequently the apparatus was modified and the open-circuit method used. This was further modified and the time of experimental observations shortened by addition of the Tissot gasometer as described by Higgins and Bates (*Am. J. Dis. Child.* **39**:71 [Jan.] 1930). This method has proved to be accurate and relatively rapid.

All methods of obtaining the basal metabolic rate of infants and young children require a special laboratory technic and technical skill. The portable apparatus that is used for older children and adults, devised by Benedict and Krogh, is manufactured by several different concerns, and although they are all based on the same general principles the mechanical constructions are different. (The Benedict-Roth portable apparatus, manufactured by Warren E. Collins, Inc., 555 Huntington Avenue, Boston, is one which has been found satisfactory.)

The different methods of obtaining the basal metabolic rate of children are not as a rule due to the type of apparatus used but to the technic of obtaining the metabolism and the difficulty of obtaining basal figures. Too large a proportion of the figures that appear in the literature do not represent basal figures, either because of lack of cooperation of the child, excitement or inexperience of the technician in handling children. The tendency of physicians to accept a single test as representing the basal metabolic rate has led to publication of much worthless material and has been commented on by Du Bois in the *Journal of Nutrition* (**3**:331 [Nov.] 1930).

The difficulties experienced in interpreting the basal metabolism of children has resulted from lack of knowledge of the physiologic processes which may affect the metabolism of the growing child. The whole problem of the normal heat production of girls has recently been reviewed by Talbot, Wilson and Worcester (*Am. J. Dis. Child.* **53**:275 [Jan., part 2] 1937) and the former has published standards for both boys and girls that approach the problem from a slightly different angle than that used in the Aub-Du Bois and the Harris-Benedict standards. Talbot believes that these standards give results consistent with clinical changes experienced in childhood. Statistical analyses show that so long as the physical development of the child is normal there is no choice between this standard, the Aub-Du Bois, or the Harris-Benedict but that in children of abnormal development, either underweight or obese, the changes are more consistent with the clinical experiences. It would seem that the use of the standards for total calories for weight and height are therefore of more universal application.

TRAUMATIC ULCERS OF LEGS

To the Editor:—A housewife aged 33 sustained an injury to the lower part of her left leg in July 1938 in a fall in her home. The injury was located on the medial aspect of the upper third of the lower part of the leg. The wound was superficial and involved only the soft tissue. This contused wound became infected in a few days and was then treated with hot packs. Since that time there has been an area about the size of a quarter (24 mm.) which does not heal. Treatment has consisted of various ointments such as peruvian balsam, allantoin and scarlet red. This area, which now really is an ulcer, becomes infected easily. On several occasions the ulcer has been treated with 10 per cent silver nitrate, a sponge applied over the dressing and an ace bandage applied to the lower leg, according to the method of McPheeters. In a few days the ulcer is clean with no evidence of infection, and granulation seems to set in, but even after several weeks of such treatment the epithelium shows no tendency to heal. The Wassermann and Kahn reactions of the blood are negative. Urinalysis is negative. X-rays show no involvement of the bone. The patient's general health is satisfactory. There is no evidence of varicosities. The patient at all times has been ambulatory. I would appreciate any suggestion you may be able to give as to treatment.

M.D., Illinois.

ANSWER.—Traumatic ulcers of the lower extremities, especially if they are located over the tibia where the skin is on a stretch and the blood supply is not active, show a poor tendency to healing. Their chronicity is maintained by secondary infection, and a wall of inflammatory induration is built around the edges. When the defect assumes the size of a quarter, it is best to immobilize the patient with the leg elevated and use continuous dressings of hot boric acid. When the granulations look healthy and the edges are not undermined, a skin graft, preferably a split graft, can be used to cover the ulcer. This procedure requires some experience in plastic surgery. The customary Thiersch graft is too thin and readily breaks down in this location.

BILIARY COLIC

To the Editor:—A woman aged 39 with a history of typhoid at 10 has had mild attacks of biliary colic almost daily for the last eight months. The attacks do not incapacitate her but are enough to make her feel miserable. She passed a renal calculus (left kidney) five years ago. Two months ago duodenal drainage showed normal response of the gallbladder to olive oil. Culture of bile is negative. The icteric index is normal. Blood cholesterol is normal. There is mild gastric hyperacidity. Dye studies show no stones. Emptying of the gallbladder is normal. The stomach is negative on x-ray examination. The urine is normal. Treatment with antispasmodics and alkalis give but little relief. Because of the typhoid would you recommend surgical operation? She has never had acute biliary colic. Can you suggest any further treatment?

M.D., New York.

ANSWER.—The patient should have an intravenous pyelogram to see whether or not the distress is reflex from the urinogenital tract. Furthermore, it may be that the patient has a dyskinesia of the sphincter of Oddi. Finally, one should consider the possibility of a duodenal ileus or stasis. The condition might be improved by the knee-chest position after meals and a suitable corset and pad to hold the stomach in a more normal position to relieve the duodenal ileus. Instead of alkalis after meals, it might be well to try diluted hydrochloric acid in suitable doses. Surgical intervention from the evidence presented does not seem justified.

INHERITANCE OF HUNCHBACK

To the Editor:—A patient has inquired whether the fact that the mother of his prospective bride has a marked kyphosis (hunchback) could conceivably reflect itself in offspring. The two children of this woman are apparently entirely normal. The cause of the kyphosis is not known. If there is any logical or statistical basis for worry, please explain.

M.D., New York.

ANSWER.—The only direct evidence as to the inheritance of the hunchback condition seems to come from the description of a pair of one egg twins by Siemens. When these twins were babies they were both normal and healthy and so much alike as to be practically indistinguishable. Later on one of them had an illness that left her a hunchback invalid, while her twin remained straight and healthy. In this case the hunchback condition was not hereditary, for one egg twins have exactly the same hereditary makeup. There probably is no cause to worry about the case in question.

ANTHRACOSIS

To the Editor:—Does bituminous coal dust cause disabling anthracosis? Are there any cases on record? If so, what are the signs and symptoms?

M.D., New York.

ANSWER.—There is evidence to show that under certain circumstances bituminous coal miners may develop a disabling pneumoconiosis sometimes called "anthracosis," or, more specifically, anthracosilicosis, a silicosis complicated by the accumulation of coal dust in the lungs. A miner's exposure to coal dust may vary from mine to mine, and disability produced may vary depending on the amount of siliceous material associated with the coal dust which he breathes.

The pathologic changes in the lungs may vary from a simple black anthracotic lung without much fibrosis to extensive, localized accumulations of coal dust in fibrotic "india-rubber-like" areas. The latter change apparently does not occur unless the miner has been exposed to quartz.

As in silicosis, dyspnea, cough productive of more or less black sputum, weakness, pain in the chest, physical signs of bronchitis, pulmonary fibrosis and emphysema are symptoms and signs that appear late in the course of the disease. X-ray study will show the degree of fibrosis. Careful sputum study by smear, culture and animal inoculation is often necessary to establish a complicating tuberculosis.

VISUAL MEMORY AFTER BLINDNESS

To the Editor:—A patient who has been totally blind for five years informs me that visual memories of objects have been gradually fading from his mind, so that now they are entirely extinct. He has no visual image of his wife, who takes care of him, nor of his friends. On questioning about his dreams, he says that though he dreams of performing certain tasks, such as drafting, he never sees objects or people. He is apparently intelligent, with no impairment of faculties. He reads braille. Is this usual in such cases and what is the explanation?

M.D., New York.

ANSWER.—Loss of visual memory is not usual among the blind. One man, blinded at 58 and now 78, states that he still has clear visual images of what he saw before he was 58 with no fading out whatever. For twenty years he has been a teacher of thousands of adult blind and states that he has never heard of such a thing. He further says that many students refer in their writings to things they used to see, and he therefore feels that loss of visual memory must be a most unusual phenomenon. It is possible that in this instance the claimed loss of visual memory may be a subconscious attempt to procure sympathy. At least such a possibility must be considered.

EPITHELIOMA OF LABIA

To the Editor:—Please advise me as to the safest method of procuring a specimen for biopsy from a patient with a suspicious irritation of the labia majora. In the event of a diagnosis of epithelioma, what would be the approved method or methods of treatment? The patient is 66 and is in fair health and strength.

M.D., California.

ANSWER.—If the suggestive area is small and the clinical appearance and history are such as to lead to a reasonable possibility of malignant disease, the safest procedure to adopt is to excise such a lesion completely. The excision may be made with a scalpel or with the electro-endotherm knife.

In the event of a diagnosis of epithelioma, the lesion will have been removed completely and no further treatment is necessary. If the lesion is too extensive to remove by a simple local excision, a small fragment may be excised carefully and examined microscopically. If the lesion proves to be an epithelioma, the best procedure is complete surgical removal if the lesion is operable. This procedure is preferable to radiation therapy when the lesion is still in an operable stage. The question of how to treat the regional lymphatic gland is much more difficult to answer. The following reference is suggested: Cutler, Max, and Buschke, Franz: Cancer—Its Diagnosis and Treatment, Philadelphia, W. B. Saunders Company, 1938, pages 413 and 414.

OSTEOMYELITIS AND SYPHILIS

To the Editor:—A man aged 52 with syphilis of unknown duration was treated in a venereal disease clinic from Oct. 9, 1936, until July 8, 1938, the last treatment being given June 10, 1938. During this time he received four courses of twelve injections of bismuth from Oct. 9, 1936, to June 10, 1938, and one course of twelve injections of bismarsen from Oct. 15, 1937, to Jan. 14, 1938. The last Wassermann reaction, June 30, 1938, with alcohol was 4 plus and with cholesterol 4 plus, and the Kline reaction was 2 plus. I may add that the patient was discharged to await a recall for further treatment and has as yet not been recalled. The patient has been suffering pain for months in the right leg. An x-ray diagnosis of osteomyelitis (syphilitic?) has been made. Biopsy reveals a nonspecific inflammatory process. Four years ago an identical syndrome (agonizing pain and swelling) existed for a total duration of two months, successively in the left forearm, the left and then the right elbow, disappearing spontaneously. How shall I treat this patient?

LEON PARIS, M.D., Bronx, N. Y.

ANSWER.—The evidence offered by the inquirer is hardly enough from which to make concrete suggestions. In view of the x-ray evidence and the previous positive Wassermann reaction, the patient should be given the benefit of antisyphilitic treatment. The previous treatment was unbalanced, in that the amount of arsphenamine received was inadequate. The patient should be given at least eight doses of arsphenamine and sixteen injections of bismuth, and with this treatment the pain in the leg should disappear if the osteomyelitis is of syphilitic origin. It is sometimes necessary to remove sequestrum surgically from syphilitic osteomyelitis. If the therapeutic test is positive, at least three more similar courses should be given. On the other hand, osteomyelitis in a patient with syphilis may be due to some other type of infection.

EARACHE AND MENSTRUATION

To the Editor:—A white woman aged 23, married, has two living children, none dead, has had no miscarriages and is in general good health. Her chief and only complaint is earache. About ten days before each menstrual period is due she begins to have a slight pain in the right ear; the pain becomes progressively worse until it is almost unbearable. The pain begins to subside until by the time the menstrual flow has started it has entirely ceased. There is no more pain for another month. The pain is always more severe at night. The patient started menstruating at 14; she has always been regular, every twenty-eight days, and usually menstruates for four days. She has never had any pelvic pain—not even the slightest cramps—at her periods. She had never had any pain in the ear prior to the beginning of menstruation but has had it every month since. She has had two children; in each of her pregnancies she had no earache. The youngest child is 5 months of age. One day after the birth of this child the earache began and ran through a cycle similar to a premenstrual cycle. The menstrual periods have not become reestablished since the birth of the last child but each month she has had the earache. Complete physical examination is essentially negative, with the exception of a moderate retroflexion of the uterus; the uterus is freely movable. There is no record of pelvic examination prior to the birth of the first child. Do you think that all the pain is referred and due to the retroversion, or that it is a delayed pain due to ovulation? Also do you think surgical correction of the retroversion will be of any benefit? Exercises, including the knee-chest position, have had no effect. Thank you for any information you may give.

M.D., North Carolina.

ANSWER.—It is quite unlikely that the premenstrual pain in the ear is referred from a retroflexed uterus. It appears, however, that this patient exhibits a unique example of the so-called nasogenital relationship. There is considerable evidence at the present time that the nasal mucosa is involved in ovarian function (Rosen, S., The Nasogenital Relationship, *Arch. Otolaryng.* **28**:556, 1938). Experimentally pseudopregnancy in rats can be produced by several sorts of stimulation of the nasal mucosa. Clinically it is well known that congestion and vasomotor changes of the nasal mucosa, especially that of the turbinates, is manifested during the premenstrual period. It is conceivable that in this patient the congestion of the nasal mucosa occurring in the second half of the menstrual cycle may effect the orifice of the right eustachian tube, thus, resulting in pain which is referred to the ear. Possibly the tissue about the orifice may be responsive to the ovarian hormones through some anomaly.

It is recommended that a thorough nasopharyngeal examination be made at the height of the patient's distress. If mucosal changes are found, it is suggested that the patient be treated as in premenstrual tension with progesterone in doses of 5 mg. intramuscularly twice a week during the premenstrual period. Vasoconstrictor drugs may also be tried.

POSSIBLE TRICHOMONAS PYELITIS

To the Editor —A woman aged 33 gives a history of a great deal of pain in the right side She has had her gallbladder removed, has had several complete and thorough examinations of the kidneys and x-ray examinations with oral dye and intravenous dye, but no definite pathologic change has ever been demonstrated. She recently had a complete hysterectomy, at which time there was no evidence of any other abnormality in the abdomen A number of years ago she had an attack of pyelitis but has been free from it until subsequent to this last operation, and, while still in the hospital, she had another severe attack. This has been repeated during the last two months, with several attacks with chills and fever, but they do not last long She has been under treatment with prontylin (sulfanilamide) and prontosil (the disodium of salt of 4 sulfamido phenyl-2'-azo-7' acetylamino 1'-hydroxynaphthalene-3',6' disulfonic acid) and mandelic acid, alkalization and the like. Recently a specimen of urine was sent to a laboratory in New York and returned with the statement that it showed an ameboid growth with pear shaped flagella thought to be Trichomonas vaginalis It was not a catheterized specimen but a vaginal plug was used *so as to get no contamination.* These were found again subsequently, and were followed by an attack of chills and fever. I believe that it is a fact that this growth does invade the bladder and attaches itself to the bladder wall, but I am wondering if it is known whether they progress up to the kidney pelvis and do the same thing there? If this is true, what is the treatment? I will appreciate any advice you can give me in reference to this.

M D., Wisconsin.

ANSWER.—From the history and observations given, there are still other possibilities than that of Trichomonas vaginalis pyelitis. The organism in question may be closely imitated by the so-called Bodo caudatus. This organism carries two flagella instead of the four of Trichomonas, is considerably smaller and cigar shaped and has no undulating membrane. It is frequently a contaminant of urine that has been allowed to stand for some time. In order to make a diagnosis Trichomonas pyelitis the trichomonas organism should be discovered in a freshly obtained catheterized specimen from the suspected kidney. If this is not possible, at least a bladder specimen should be positive for this organism. A good way to find Trichomonas in a smear is to mix one drop of 0 1 per cent of saffron with a thoroughly centrifuged sediment of the suspected urine. When examined wet under coverglass, Trichomonas will appear clear.

Retrograde pyelography with plates made in both horizontal and upright positions are also indicated, together with cultures of each kidney.

Trichomonas pyelitis is a rare condition but a few cases have been reported. Suggested treatment is lavage of the affected kidney pelvis with 2 per cent mercurochrome once or twice a week followed by vesical instillation of 1 : 1,000 silver nitrate. Also it is of value to lower the *p*H by the use of ammonium chloride, sodium acid phosphate or whatever acidifying agent is available. It might also be suggested that lavage of the kidney could be done with 1 per cent silver nitrate. The source of infection should be looked for in the cervix and vagina and in the genitals of the male sexual partner.

PREGNANCY AND MARITAL SYPHILIS

To the Editor —A secundigravida primipara aged 25 expects confinement May 10. Her husband contracted syphilis four years ago (prior to marriage) and, because of lack of cooperation, has received only spasmodic treatments for the disease, consequently the Wassermann reaction of his blood is still 4 plus *The patient's Wassermann reaction has always been negative, however, because of the husband's history, she received adequate and accepted therapy during her first pregnancy, which terminated in a stillbirth, the baby being grossly normal and the placenta negative for spirochetes Labor was easy and spontaneous.* The patient is now four and one half months pregnant *Her Wassermann reaction is negative and the husband's is 4 plus* Should this patient be treated as having syphilis in order to insure the birth of a living child? If she never did contract syphilis from the husband (he had been partially treated), would *injections of neoarsphenamine* or bismuth or both have an actual harmful effect on the fetus or mother or both? In short, should this woman receive antisyphilitic therapy? Any suggestions would be greatly appreciated.

FRANK J CLARKE, M.D , Brooklyn

ANSWER—Naturally if this patient did not have syphilis injections of neoarsphenamine and bismuth would not be necessary It is not felt that they would have any harmful effect on the fetus or mother, however, and since the husband's syphilis is of such recent date—five or six years at the most—he is still in the period of possible relapse *Also, since he had inadequate treatment, it seems advisable to treat the patient up until the birth of the child* In a case of this type it probably would be well to have an exclusion *test done on the mother.* It may be that, because of her pregnancy, the disease is partially under control for the time being and that the test would reveal nothing but that she has a low grade type of syphilis. On that account and because of the possible danger to the child, treatment for syphilis is recommended. It should be started with a course of arsenicals, followed with a short course of bismuth and ending up with arsenicals until the birth of the child.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, May 20, page 2086.

Washington January Examination

Mr. Dave S. Cohn, acting director, Department of Licenses, reports the written examination held by the State Board of Medical Examiners at Seattle, Jan. 9-11, 1939. The examination covered seven subjects and included seventy questions. Thirteen candidates were examined, all of whom passed. Seven physicians were licensed by reciprocity and four physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.
College of Medical Evangelists		(1938)
Northwestern University Medical School	(1938),	(1938)*
Rush Medical College		(1937)
University of Illinois College of Medicine		(1926)
Harvard Medical School		(1925)
Tufts College Medical School		(1921)
Ohio State University College of Medicine		(1938)†
University of Oregon Medical School		(1938)†
Dalhousie University Faculty of Medicine		(1935)
McGill University Faculty of Medicine		(1934)
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin		(1931)
Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn		(1920)

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Stanford University School of Medicine		(1935)	California, (1936) Minnesota

Book Notices

Lead in Food. By G. W. Monier-Williams, O.B.E., M.C., M.A., Ministry of Health, Reports on Public Health and Medical Subjects, No. 88. Paper. Price, 1s. Pp. 51. London: His Majesty's Stationery Office, 1938.

The problem of lead in foods is attracting a great deal of attention and the British Ministry of Health deserves credit for sponsoring the present brief but authoritative account of what is known about the subject. The author has reviewed the literature on the absorption, excretion and storage of lead in the body. The section on lead in the body includes a discussion of the use of alloys, solders, enamels and glazes containing lead in connection with the manufacture, storage, transportation or cooking of food; the use of ingredients in the production of which materials containing lead have been used, or which have been manufactured in lead lined vessels; the presence on fruits and vegetables of spray residues containing lead arsenate or other lead compounds; the exposure of food to dust containing lead, such as that produced by the weathering of lead paint, and the amount of lead in sea foods. The author describes a modification of the diphenylthiocarbazone (or dithizone) method for the determination of minute amounts of lead. The lead is isolated from the ashed material by means of dithizone but subsequently is converted to the sulfate and finally estimated colorimetrically as the sulfide. Data are provided on the lead content of a number of foods as determined by this method. In a list of 118 foods analyzed, thirty-five are reported as having a lead content that is nil. In the light of recent investigations in the United States, practically every food that has been examined has been found to contain a detectable amount of lead. It would seem that the author's method was not sensitive enough to detect the traces which other methods have been able to determine. There is considerable interest to the author's conclusion about the limits for lead in foods from the point of view of public health. The opinion is advanced that a total intake of 1 mg. of lead daily, presumably by adults, must be regarded with suspicion and efforts should be made to eliminate the sources of lead.

Leben und Ernährung. Von Dr. Max Winckel. Bücher der Hygiene und Volksernährung, Band I. Herausgegeben von Max Winckel. Paper. Price, 1.80 marks. Pp. 86. Berlin: Deutsche Verlagsgesellschaft m. b. H., 1938.

During times of stress proclamations are issued by governments or words of advice are offered by patriotic individuals which relate to the selection of foods. Usually the suggestions are bad in either case. They can be excused only because of the exigencies of the situations which produce them. More than a century ago there occurred the famous recommendation made in France about subsistence on gelatin, which two scientific commissions later showed to be impossible. More recently there were during the World War restrictions on the dietary habits of all people. Even America felt the effects to a moderate extent. Recipe booklets for wheatless bread are interesting items for the collection of any nutritionist interested in the history of diets. So also are accounts of disasters resulting from the misguided advice to eat such substances as rhubarb leaves. The accounts of human dietaries in Germany and Austria during the World War are replete with examples of the horrible effects of war, particularly on children. The present book of dietary advice to the German people may be excusable on the basis of what must be done to feed the people, but it is neither scientific nor completely accurate. It is understood from the foreword that it is the first of a series of monographs on food products intended for the average German reader. The other monographs in the series will be on the garden and health, biochemistry of the kitchen, the daily diet of the family, diet kitchens and subsistence of the masses, and nutrition of the mother and child. The present book is a tract devoid of illustrations or charts but containing many italicized statements. It is obviously propaganda by the German state to persuade people that restriction of calories and the eating of foods which are available rather than those which are more difficult to obtain is nutritionally advantageous. The reader is told repeatedly that it is his responsibility to the state to maintain himself in excellent nutritive condition. This is to be done by reducing the daily intake of calories and increasing the consumption of those products which are readily available in present day Germany. It is recommended that the fat content of the diet should be reduced from its present average level for the adult of 100 Gm. daily to 80 Gm. and that the calories should be reduced from 3,200 to 2,900 each day. It is also recommended that the daily protein content of the diet should be reduced to 80 Gm. and should be secured from milk and potatoes instead of meat. For the most part coffee and tobacco are banned. While some of the arguments presented have some factual basis, for many assertions the support is relatively poor. But the reader is assured that by following the advice which is given he will aid the führer in his "deliverance" program for national socialist Germany.

The Surgery of Oral and Facial Diseases and Malformations: Their Diagnosis and Treatment Including Plastic Surgical Reconstruction. By George Van Ingen Brown, D.D.S., M.D., C.M., Plastic Surgeon, Children's, St. Mary's, Columbia, and Milwaukee County Hospitals, Milwaukee, Wisconsin. Fourth edition. Cloth. Price, $10. Pp. 778, with 1,031 illustrations, including 12 colored plates. Philadelphia: Lea & Febiger, 1938.

Although this edition contains a few less pages than previous editions, it is much more complete. The author has utilized his extensive clinical experience with pathologic conditions about the head and neck, and especially of the face and mouth, to present what comprises largely the sum and substance of present day information concerning faciomaxillary diseases and surgical procedures for their alleviation. As stated in the preface, the subjects are presented in such order and with sufficient descriptive matter that the book is well adapted to students' requirements in classroom instruction; at the same time it is suitable for practitioners. It is also arranged in such a manner as to supply a reliable source of reference for the diagnosis and treatment of pathologic changes in the oral and facial regions and also to serve as an operative guide for those specializing in the surgical procedures of these regions. The chapters dealing with oral and facial neoplasms and diseases of other types have been revised and condensed, and a number of chapters concerned with plastic operations of the various portions of the face and neck have been added. In addition the chapters on harelip, cleft palate and other congenital defects and deformities have been made more complete. The text is elucidated and rendered more graphic by a greatly increased number of illustrations, which are decidedly better than those contained in previous editions. A number, however, and especially some of the colored plates, do not approach the high standard of the rest of the work. In general the subject matter is clearly and concisely presented, and the author is an authority in this field. The book should be a valuable addition to any medical library.

An Introduction to Bacteriological Chemistry. By C. G. Anderson, Ph.D., D.Bact., Lewis Cameron Teaching Fellow, Bacteriology Department, University of Edinburgh. Cloth. Price, $4. Pp. 278. Baltimore: William Wood & Company, 1938.

This well written, compact and well organized textbook is the outcome of a course of lectures on the subject. The first five chapters discuss hydrogen ion concentration, oxidation-reduction and the general composition of bacteria, fungi and yeasts briefly but clearly. The next four chapters deal with the nutrition of bacteria, treating growth factors, autotrophic and heterotrophic bacteria, and adaptive and constitutive enzymes. The subject of bacterial respiration is especially well developed from the point of view of the fundamental chemical reactions involved. Nitrogen metabolism is discussed from the point of view of assimilation, sparing action and the usual paths of deaminization and step by step oxidation. Carbohydrate metabolism and alcoholic fermentation are presented from the truly modern biochemical view. The specific and remarkable activities of some fungi in fermentation processes and some of the industrial applications are considered briefly. The proteins of micro-organisms and lipins are treated briefly but satisfactorily. The polysaccharides in these forms are discussed satisfactorily under the subdivisions of true complex polysaccharides and specific soluble aldobionic acid derivatives. The unsatisfactory state of our knowledge of the chemistry of bacterial pigments is emphasized. Antigens, haptens, antibodies, complement and the mechanism of antigen-antibody reactions the

author treats in the main on the chemical basis, which has developed as a result of Landsteiner's investigations. A practical discussion of the isolation and identification of metabolic products and an excellent index close the book. The author rarely refers to original papers, but in most cases the chapters close with a few references to monographs or review articles. Every bacteriologist and biochemist could well afford to read this brief but excellent treatment of a complex and rapidly developing aspect of bacteriology.

Der Rheumatismus: Sammlung von Einzeldarstellungen aus dem Gesamtgebiet der Rheumaerkrankungen. Herausgegeben von Professor Dr. Rudolf Jurgens, Stellv. Direktor der Universitatsklinik fur natürliche Heil- und Lebensweisen Berlin. *Band I: Übungstherapie bei rheumatischen Erkrankungen.* Von Geheimem Sanitätsrat Dr. P. Kohler. *Band II:* Anleitung zur klinischen Analyse des Infektiosen Rheumatismus. Von Professor Dr. med. A Slauck, Chefarzt des Landesbades und Leiter des Rheumaforschungsinstituts in Aachen. Boards. Price, 5 marks each Pp. 100, with 22 illustrations; 78, with 6 illustrations. Dresden & Leipzig: Verlag von Theodor Steinkopff, 1938.

The author believes that physical and occupational therapy play an important part in the treatment of rheumatism; therapy serves as an aid to physiologic healing. One chapter is devoted to the functional role of bones, joints, muscles and nerves. The formulation of a logical plan of action is necessary for each case. The questions which must be considered specifically are the need for rest or exercise, position, the use of traction, extension or hyperextension and the application of some form of strapping or bandage. A good expository outline briefly evaluates passive and active exercises, both local and general, relaxation, circulatory factors, combination exercises and group exercises. Chronic arthritis can be alleviated by specific forms of physical therapy. The final chapter in the first volume consists of an outline of regional exercises and may serve as a ready reference for routine procedures. The second volume is by Dr. Slauck, who is chief of the national baths and head of the research institute for rheumatism at Aachen. His purpose is to clear a way for the general practitioner through the confusion, since the general practitioner is the first to see patients with rheumatism and is in a position to institute early therapy. Prophylaxis is difficult, since one cannot anticipate which source or focus will give rise to the rheumatic condition. Slauck believes that acute rheumatic fever has a focal source of infection. The chief foci, in his opinion, are sinuses, teeth and tonsils, which cause a "focal toxicosis" which spreads by the hematogenous route. In cases of early involvement the foci must be found and eradicated before any other treatment is considered. This is true also in cases of chronic rheumatism, but physical therapy and balneotherapy may be started at once. The author states that too much should not be expected of antifocal therapy.

Pathologische Histologie: Ein Unterrichtskurs für Studierende und Arzte. Von Dr. Max Borst, o. o Professor der allgemeinen Pathologie und der pathologischen Anatomie an der Universitat Munchen. *Third edition. Paper. Price, 75 marks.* Pp. 522, with 361 illustrations. Berlin: Julius Springer, 1938.

This textbook, which first appeared in 1921, was described by Borst as an attempt to develop a book which would emphasize pathologic histology. He said at that time, furthermore, that a better understanding of etiology, pathogenesis and function would require a more detailed microscopic analysis of morbid processes. This edition is an amplification of the material with these ends in view. Almost all the illustrations are in color. They are, however, not photomicrographs but are mostly drawings which at best are poor substitutes for reality. The book deals essentially with special pathology, and no attempt is made to present a general point of view. The author has given a brief and incomplete description of the normal structure of each organ, seemingly an unnecessary feature for the student, who presumably has studied histology before beginning his studies of pathology. The general treatment of the particular diseases is extremely brief and there are no references to the works of others. The main value lies in the concentration on histologic pathology, and many pathologists will be interested in the way Borst handles this phase of pathology. As a textbook for American students, however, the book is entirely too skimpy and inadequate to be of much value.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. *Volume X:* Poisons Legislation to Rosacea. Cloth. Price, $12 Pp. 694, with 91 illustrations including 11 plates. Toronto & London: Butterworth & Co. (Publishers), Ltd., 1938.

This volume covers such important topics as poliomyelitis, postmortem examinations, pregnancy, diseases of the prostate, psychiatry and psychoanalysis, pyelitis, radiology, refraction, resuscitation and rheumatic infection. The consistency and uniformity of the discussions are amazing when one considers the vast scope of the encyclopedia. It is perhaps due to the general editorship of Sir Humphry Rolleston and the high order of the groups of consultants and associate editors that this result has been achieved. Unfortunately this volume suffers, as have other encyclopedias, from the fact that medical progress is now so rapid that some of the material is well nigh obsolete by the time it is published. Thus the article on poliomyelitis makes no reference whatever to the recent attempts to block the path of entry by caustic solutions, nor is there any reference in the article on psoriasis to recent endeavors to control the condition by high doses of vitamin.

A Textbook of Neuro-Radiology. By Cecil P. G. Wakeley, D.Sc. F.R.C.S., F.R.S.E., Senior Surgeon, King's College Hospital and West End Hospital for Nervous Diseases, and Alexander Orley, M.D., D.M.R.E., Radiologist, West End Hospital for Nervous Diseases, London. Cloth Price, $8. Pp. 336, with 229 illustrations. Baltimore: William Wood & Company, 1938.

An adequate compendium of neuroradiology would be welcome to neurologists as well as to roentgenologists. However, this volume, a first attempt at supplying the need, does not succeed. The text contains many quotations from the literature but does not impress one as representing a thorough and detailed experience in the field. Further evidence for this assumption is the paucity of good illustrative roentgenograms of the skull demonstrating individual pathologic processes The text is written in a terse style and conditions of interest are too briefly discussed. The book is not a substitute for a knowledge of the literature. It is not highly recommended but may be of some use for beginners in the field until they acquire personal experience.

Silikosen i den danske Industri. Af V. Stub-Christensen. [Silicosis in Danish Industry.] Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. Paper. Pp. 312, with 70 illustrations. Copenhagen: Levin & Munksgaard, 1937.

A thesis in connection with the acquisition of a doctor of medicine degree, this book embraces a three year study at the Silkeborg Sanatorium in Denmark. The period of observation ended in 1932, although publication was not made until 1937. The author says that much less concern was exercised over silicosis, asbestosis and other forms of pneumoconiosis in Denmark than in several other countries. Appraised at this later time, his own grasp of such diseases and his understanding of the underlying pathologic change appear to have been far in advance of the general level throughout the world in 1931. The major industries studied were sandblasting, molding (foundries), stone cutting, sandstone and granite cutting, millstone work, cement making, the manufacture of cleansing powders, metal grinding, including instrument grinding, and brick making. The book has four major divisions: the general clinical and laboratory aspects of dusty lung diseases, a description of the industries involved, a careful recording of case histories by industries, and the presentation of seventy beautiful illustrations, chiefly roentgenograms but including reproductions of gross and microscopic tissue preparations. The lament often arises that roentgenograms of silicotic chests cannot be produced with high fidelity. The ones in this book are far superior to those usually found. There is a fine presentation of the cases of 300 disabled workers, of whom 70 per cent were decidedly disabled and 30 per cent mildly so. Sixty-two per cent had silicosis, 3 per cent tuberculosis alone and 13 per cent silicotuberculosis. Because of language difficulties the book cannot be generally recommended to the physicians of the United States, but for physicians, public health workers and others concerned in the international aspects of dusty lung diseases here is the Danish entry.

A Textbook of Pathology for Use in Schools of Nursing. By Armin V. St. George, M.D., Lecturer in Pathology, Bellevue School of Nursing, New York City. Second edition. Cloth. Price, $1.75. Pp. 238, with 20 illustrations. New York: Macmillan Company, 1938.

The author presents pathology clearly, covering the majority of the material that is included in the standard textbooks. In great part it is expressed in a form that is too brief and inadequate for present day teaching requirements in training schools for nurses. The chapter on the urinary tract stands out above the others. There is an anatomic, physiologic, pathologic and clinical correlation which gives one a fairly good insight into the various entities included under the broad heading Bright's disease. The concluding chapter is an added useful feature describing essentially clinical pathologic methods and their interpretations.

Laboratory Manual of Hematologic Technic Including Interpretations. By Regena Cook Beck, M.A., M.D., Pathologist to Stuart Circle Hospital and Director of the Stuart Circle Hospital School of Medical Technology, Richmond, Virginia. With a foreword by Frank W. Konzelmann, M.D., Professor of Clinical Pathology, Temple University, Philadelphia, Pa. Cloth. Price, $4. Pp. 389, with 79 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

A number of concise and comprehensive textbooks on hematology have recently been written, but this is the first comprehensive textbook on hematologic technic. While written expressly as a manual for technicians, it will undoubtedly find a greater field of usefulness. The data are current and well organized. The author has been able by careful editing to present a maximum amount of well illustrated material in a minimum of space. At the end of each chapter are lists of questions for the purpose of aiding the reader to fix the salient facts. Lists of defined terms throughout the book will enable the technician to become familiar with a workable hematologic vocabulary. The book is highly recommended as a hematologic manual for laboratory technicians and a convenient source of information on hematologic procedures for medical students and physicians.

Reflektorische und algetische Krankheitszeichen der Inneren Organe. Von Professor Dr. K. Hansen und Dr. H. von Staa. Paper. Price, 26 marks. Pp. 270, with 127 illustrations. Leipzig: Georg Thieme, 1938.

This monograph is concerned with the well known investigations of Head and Mackenzie, some of the observations of Knotz and further observations by the authors on reflex and pain symptoms in diseases of various organs. The introduction deals with the historical development of the subject. The next discussion is devoted to methods. The difference in the size of the pupils was recorded by infra-red photography. The photographs are instructive and sharply defined. Many physicians will be surprised at the finding of mydriasis on the same side in 88 per cent of all cases of unilateral organic disease. Other unilateral symptoms noted were widening of the palpebral aperture, facial spasm, postural changes, asymmetrical respiratory motions, and herpes. The authors describe their technic of detecting differences in tissue tension (besides muscle). Vasomotor disturbances, pilomotor reflexes, referred pain and, finally, the so-called viscerovisceral reflexes are described. The greatest part of the monograph is devoted to case reports and tables concerning reflex and pain symptoms of disease in various organs. There are abundant schematic diagrams and an adequate bibliography. The basic clinical material is well documented and analyzed, and the neurologic analysis of the described symptoms is well done. The monograph represents a carefully conducted study which should interest a large number of practicing physicians.

Mental Nursing in Observation Wards. By I. M. Sclare, L.R.C.P.S., Mental Observation Wards, Stobhill Hospital, Glasgow, N. Foreword by A. S. M. Macgregor, O.B.E., M.D., D.P.H., Medical Officer of Health, Glasgow. Cloth. Price, $2. Pp. 259. Baltimore: William Wood & Company, 1938.

This volume was written for a special group of nurses, those who are working with mental patients in general hospitals. It does not seem to fit its purpose adequately and is probably not as good a book for educating mental ward nurses as those produced in this country by Sands and Noyes. It is a brief summary of the various types of psychoses. Not much detail is given in the matter of nursing and the special care of patients. A short chapter dealing with what the author calls normal psychology is a much too brief sketch of basic psychodynamics. The chapter on the anatomy and physiology of the nervous system is too short to be of much value. The last chapter is even more cursory and deals with the duties of nurses in mental observation wards. The volume is too inadequate to give a nurse much idea of her duties. Either the work done in the observation wards in the British Isles is not as thorough as that done in hospitals such as Bellevue and Cook County, or this book is not a fair demonstration, for it certainly does not cover the involved technics required for properly dealing with the patients brought into the general hospital to be cured in a short time or to be committed permanently to hospitals for the insane. The style is good and the diction simple, but the book seems to serve no purpose in our American mental health program.

Anatomia del neonato. Da Francesco Bellelli. Prefazione del Prof. Sen. Giulio Salvi. Paper. Price, 30 lire. Pp. 229, with 109 illustrations. Naples: G. U. F. "Mussolini" Sezione Editoriale, 1938.

An "Anatomy of the Newborn" should be a welcome contribution not only to anatomists but to obstetricians and pediatricians as well. Bellelli's book represents one of the first attempts to gather the hitherto scattered data from original articles, textbooks of anatomy and handbooks. The bibliography comprises 163 titles, most of which refer to contributions by Italian authors. The pertinent literature is fairly considered throughout the book, although there are certain omissions. For instance, Scammon and Calkin's valuable data on body dimensions of the newborn are not included. One misses a consideration of specific growth rates and of the relative position of the newborn with respect to prenatal and postnatal growth rates of the body as a whole or of the various systems. Only the general changes in the major proportions between birth and adulthood are discussed. The largest part of the book constitutes a compilation and discussion of previously published observations. Likewise most of the illustrations are taken from previous authors. Their quality leaves something to be desired. It is regrettable that the author has failed to supply much needed original ones in this field in spite of the many dissections which he apparently has made. The book is concerned only with descriptions of gross anatomy and topographic relations. The subject matter is subdivided into ten chapters, on definition of newborn, external form and body proportions, osteology, articulations, myology, angiology, splanchnology, glands of internal secretion, neurology, and skin and sensory organs. The author defines newborn as born at term and having accomplished for the first time all or some of the elemental vital acts.

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Röntgenatlas der Asbestose der Lungen. Von Prof. Dr. Erich Saupe. Fortschritte auf dem Gebiete der Röntgenstrahlen, Ergänzungsband LIV. Herausgegeben von Prof. Grashey. Paper. Price, 19.50 marks. Pp. 99, with 52 illustrations. Leipzig: Georg Thieme, 1938.

In this monograph Saupe introduces his thesis with a brief historical account of the mineral asbestos and a chapter devoted to its geology, mineralogy, chemistry and technology. Subsequent chapters consider the pathologic anatomy of the disease asbestosis, its clinical symptoms, signs, complications, x-ray appearances, prognosis and therapy. There are chapters on the difference in individual susceptibility to the dust, the medical and technical methods for control of the disease and the asbestos body and its clinical significance when found in the sputum. The author stresses the important points adequately. The mineral is classed as a fibrous magnesium silicate which on inhalation causes diffuse fibrosis of the pulmonary tissue. The fibrosis is most pronounced in the interalveolar and interlobular septums of the lung. Clinically there is no characteristic subjective or objective evidence. In cases of far advanced involvement there are often a chronic slightly productive cough, appreciable dyspnea, decreased chest resonance and fine or coarse vesicular breath sounds. The monograph gives a detailed description of the x-ray appearances of the disease. In the early stages, or first degree asbestosis, an increase is noted in the pulmonary markings at the base of the lung. As the disease progresses these markings become more prominent and a fine mottling appears, which in the late stage, or third degree asbestosis, imparts to the roentgenogram a diffuse haziness. These various changes are depicted in the atlas, in which forty-four case histories are presented. The roentgenographic reproductions are exceptionally good, although in numerous instances they do not

allow visualization of the changes described in the text. This is pardonable, since at best it is difficult to reproduce the distinctive morphologic details shown on the x-ray film. The bibliography is recent and sufficient for further study of the subject. The monograph should prove of distinct value to all those who have to do with pulmonary disease due to the inhalation of dust, for it provides a brief and concise discussion of what is known about asbestosis.

Lærebok i generell bakteriologi og serologi. Av Th. Thjøtta, Dr. med. [Textbook on General Bacteriology and Serology.] Cloth. Pp. 384, with illustrations. Oslo: Fabritius & Sønners Forlag, 1938.

The history of bacteriology, the morphology and growth of bacteria, infection and immunity and hypersensibility are considered. The presentation is systematic and comprehensive but not dogmatic. The author is evidently a good teacher; his style is lucid and lively. Besides instructive illustrations of technical matters, mostly photographs, are portraits drawn by the author of many of the investigators referred to in the text, with thumbnail biographic sketches in footnotes. A companion volume will follow, dealing with special bacteriology and immunology. This one gives an excellent summary of general bacteriology and serology in their relation to practical medicine.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Failure to Discover Redislocation of Shoulder Joint.—The plaintiff injured his right shoulder and twelve days later, May 29, employed the defendant, a physician, to treat him. The defendant examined him with the aid of a fluoroscope and found a subglenoid dislocation of the right shoulder joint. The physician, according to his own testimony and that of his nurse, reduced the dislocation by manipulation. He did not examine the plaintiff further to determine whether reduction had been accomplished other than to observe the freedom of movement of the joint when the plaintiff placed his right hand on his opposite shoulder and on the top of his head. There was evidence that he warned the plaintiff of the danger of redislocation and advised him to refrain from working and to return in three days. Later, the plaintiff suffered a redislocation of his right shoulder joint, apparently while still under the care of the defendant although he had also consulted a chiropractor. In September roentgenograms, which the defendant for the first time caused to be taken, showed a dislocation of the right shoulder joint. By that time the muscles of the injured arm had begun to atrophy and an operation, the success of which was doubtful, was necessary if the dislocation was to be reduced.

For failure to discover the redislocation the plaintiff sued the defendant. From an order of the trial court overruling his motion for a directed verdict and from a judgment in favor of the plaintiff, the physician appealed to the Supreme Court of Oklahoma.

The testimony of the two parties as to what occurred was conflicting. The plaintiff claimed that he derived no relief from pain on his first visit to the defendant and that he returned for treatment five or six times during the ensuing four months, always insisting that there was still something wrong with his arm and, until his visit in September, receiving assurances from the defendant to the contrary. The defendant, however, testified that the plaintiff did not return for treatment after May 29 as directed but remained away until September. The Supreme Court could not agree with the defendant's contention that the evidence was insufficient to warrant the trial court in submitting the case to the jury. The testimony adduced by the plaintiff tended to show that the defendant attended the plaintiff at various times between May and September and that the plaintiff's right shoulder joint was redislocated during that period but the physician failed until September to discover its existence. If, said the court, by methods known to the physician a redislocation could have been discovered and he failed to use such methods, then he was guilty of negligence.

Although the medical testimony established that in most cases of this type a physician can ascertain by manipulation, such as the defendant claimed he used, whether or not a shoulder joint is dislocated, some of the testimony tended to show that the use of roentgenograms is probably the best method of making this determination. By his own testimony the defendant in effect admitted that, if there was any doubt as to whether or not a dislocated shoulder had actually been reduced, it would be negligence to fail to take roentgenograms. In the judgment of the court, therefore, the evidence, when considered in the light of every reasonable inference favorable to the plaintiff, was sufficient to raise a question in reasonable minds as to whether or not the defendant had been negligent.

The defendant contended that, even though he was negligent, there was no evidence from which the jury could determine whether the condition of the plaintiff's arm was due to the character of the original injury or to the defendant's lack of care and skill in treating it. This contention, answered the Supreme Court, ignored the undisputed fact that the condition of the dislocated shoulder joint was aggravated by failure to reduce it and by allowing it to remain dislocated for some months, and that the plaintiff's chance of permanent complete recovery was thereby greatly decreased.

In the opinion of the court, the evidence warranted a verdict in favor of the plaintiff. The judgment of the trial court in favor of the patient was therefore affirmed.—*Stagner v. Files (Okla.), 78 P. (2d) 418.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Clinical Types of Circulatory Failure and Their Treatment. W. G. Harrison Jr., Birmingham —p 305

Thyroid Therapy in Hypothyroidism and Cretinism.—Brown and his colleagues studied psychologically twenty-nine cretins and four "juvenile hypothyroid" children who were being actively treated with thyroid. The psychologic tests were given over a period of from one to seven years to determine by quantitative measurement both the amount and the nature of their mental development. These observations support the following conclusions. 1. Cretins if treated are not all predestined to a fixed low mental age. A small proportion of them may develop normally. 2. There is evidence that early recognition of the abnormal condition and active and persistent treatment thereafter are the important factors in producing ultimate mental development. 3. There are a number of factors which may account for the failure of some children to respond to treatment even though it is initiated early. 4. In general, there was a slight increase in the intelligence quotient during the period of treatment. The increase was greatest for those who began treatment early. Even with treatment, most of the children remained severely retarded, having intelligence quotients below 70. The chances are that at maturity their mental level will not be much above 10 or 11 years. 5. There is no evidence that cretins have any special aptitudes or abilities. The retardation seemed general. 6. The mental growth curves seemed to have the same general shape as the curve for the average child except that they were at a lower level. 7. Examination of a number of the siblings indicated that the cretins did not come from families of low intellectual status. 8. In a study of thirteen cretins there appeared to be some relation between development of carpal bones and mental age.

Diphtheria Scratch Test.—The diphtheria scratch test is performed and read in the same manner as the Pirquet test for tuberculosis, except that diphtheria toxin is used. The work that Grozin reports is based on investigations carried out by Reh. The scratch test was performed as a routine on 100 children at the Queens General Hospital and was found to compare favorably with the Schick test. Regardless of the illness for which these patients were admitted to the hospital, there was never any unfavorable reaction to the test. The material used for testing was a toxin containing 30 flocculating units per cubic centimeter, originally of 1,200 minimum lethal doses per cubic centimeter. The results as compared with those of the Schick test were as follows: There was complete agreement in 92 per cent of the cases. In one case there were a positive Schick reaction and a negative reaction to the scratch test. However, this patient had been immunized with 1,200 units of antitoxin after the positive Schick reaction and the scratch test was done several days later. As to the other cases in which there was disagreement, the Schick reaction was negative and the scratch test positive in four cases and the Schick reaction questionably negative and the reaction to the scratch test positive in two cases.

Mortality from Respiratory Diseases.—Herrington and Moriyama studied the statistical relationship between mortality from several diseases of the respiratory system and certain climatic and socio-economic factors in the United States Registration Area (forty-four states) for the period from 1921 to 1930, inclusive. The diseases selected for study were influenza, bronchopneumonia, lobar pneumonia and asthma. In view of the high incidence of bronchopneumonia during the first year of life, mortality rates for bronchopneumonia have been classified in two age groups (less than 1 and more than 1 year of age). States with high influenza mortality are all Southern states, while low mortality rates are, in general, shown by the states along the North Atlantic seaboard. The states having high mortality rates for bronchopneumonia and lobar pneumonia are located in the northeastern section of the country. There is no evidence of a geographic distribution in the group of states with low pneumonia death rates. In asthma mortality New York, Massachusetts and three other New England states are among the five states showing low rates. There does not appear to be a definite regional concentration of states with high mortality rates from asthma; two Southwestern states, Arizona and Colo-

rado, lead the list. The asthma death rate in Arizona is conspicuously high as compared to the rates of other states. Bronchopneumonia and lobar pneumonia mortality are associated with the more densely populated urban areas. The coefficients in the climatic panel indicate that all the respiratory disease mortality rates are associated with normal temperature. There is no evidence of a significant association between normal temperature and pneumonia mortality in the zero order correlation analysis, but both bronchopneumonia (more than 1 year) and lobar pneumonia are highly and negatively correlated with normal temperature. Influenza mortality, on the other hand, is definitely associated with normal temperature. Asthma is not directly correlated with normal temperature but is definitely correlated with solar radiation. In the socio-economic panel all the pneumonias are decidedly associated with some index of urbanization or population density. Influenza, on the other hand, is inversely correlated with the degree of urbanization. These results clearly show that there is a definite difference in the spatial distribution of the diagnoses of pneumonia and influenza, respectively. In every case except that of asthma the socio-economic group of factors is of greater statistical importance than the climatic group of variables.

Trichinosis in the Chicago Area.—In an attempt to determine the incidence of trichinosis in the Chicago area Hood and Olson carried out the digestion and pressed muscle methods on from 10 to 20 Gm. of diaphragms of 428 unselected necropsies performed at several Chicago hospitals. With these methods 16 per cent of the diaphragms were found infected with the larvae of Trichinella spiralis. Of the 428 samples investigated, forty-eight were from infants less than 1 year of age. Four (8.3 per cent) of these contained trichina larvae.

Antianemic Effect of Yeast in Pernicious Anemia.—Wintrobe gave dehydrated brewers' and bakers' yeast, as well as extracts of these substances, to fifteen patients with pernicious anemia in relapse and to eight with little anemia. Maximal hemopoietic responses occurred in five patients given dehydrated brewers' yeast in amounts of 1 or 2 Gm. daily per kilogram of body weight. Submaximal effects occurred in two other patients who subsequently were found to respond inadequately to liver. Little response was observed in three patients who likewise failed to respond to oral liver therapy. In only one patient was liver extract, given by mouth, more effective than brewers' yeast and in one resistant patient desiccated hog stomach was somewhat more effective than brewers' yeast. Nine patients receiving from 0.3 to 0.8 Gm. of yeast daily per kilogram of weight as maintenance therapy have remained well to date, from four to ten months. A bakers' type of yeast failed to cause well marked hemopoietic effects in six patients, four of whom subsequently did not respond even to oral liver therapy but two of whom responded to brewers' yeast. Reticulocytosis occurred in two patients given yeast extracts parenterally but a significant increase in the number of red corpuscles did not follow. A significant hemopoietic effect has not been produced by the oral administration of extracts of yeast which have been prepared so far. The author presented his observations because of the bearing they may have on an understanding of the disease pernicious anemia rather than with the purpose of proposing a new form of treatment.

Vitamin C Deficiency.—McGovern and her associates cite the cases of a mother and five children in good financial circumstances who presented varying degrees of hypovitaminosis C, resulting from a familial distaste for and consequent restriction of foods rich in this vitamin, citrus fruits. Since the mother required daily about 500 mg. of crystalline ascorbic acid intravenously to bring about chemical saturation and the disappearance of scorbutic symptoms and later relapsed while receiving 1,000 mg. orally each day, the authors raise the question whether this is due to a metabolic peculiarity of this individual which changes the vitamin into a nonantiscorbutic form or whether the potency of the synthetic substance may be altered by mechanical handling, storage conditions or as yet unrecognized factors in the methods of administration, or, thirdly, whether a deficiency of some factor other than synthetic vitamin C produced the scorbutic-like syndrome in this patient. After this patient had been under treatment for five months they made studies of her five adult children, all of whom complained of lack of strength and frequent respiratory infection. Since diagnosis of their mother's vitamin C deficiency, fruit juices had been taken about twice a week. Vitamin C saturation tests showed that all were subnormal or low-normal, and with the capillary fragility test two exhibited marked fragility, two marginal and one normal. A course of treatment with large doses of crystalline ascorbic acid was followed by normal responses in every case and disappearance of symptoms.

Specific Treatment of Types II, V and VII Pneumonia.—Brown and Finland used specific serums, sulfanilamide or both in the treatment of 148 cases of type II, eighty-one of type V and seventy-nine of type VII pneumonia. The mortality among the 148 patients treated with serum was 19 per cent as compared to 36 per cent among sixty-four contemporary patients not treated with serum. Only 14 per cent of 121 patients treated with serum before the end of the fourth day died. The greatest reduction in mortality appeared to be in patients between 20 and 60 years of age. The deaths among the serum treated patients occurred chiefly in patients with other serious complicating conditions and in those who were in poor general condition when the treatment was begun. Untoward reactions to serum injections were more frequent in type II cases than in the type I cases. Concentrated rabbit serums were used in the treatment of nine patients, including four with bacteremia. None of these patients died. The experience with sulfanilamide in eight suggests that this or similar drugs may have some usefulness as an adjunct to specific serum in the treatment of certain severe type II cases. Among the eighty-one patients with type V pneumonia treated with serum the death rate was 10 per cent as compared with 41 per cent among 234 patients not treated with serum, which included contemporaneous cases and those occurring in the six years before the introduction of specific serum. Following serum treatment, clinical improvement was rapid and complete. Deaths occurred only when specific treatment was undertaken in the face of severe complicating conditions or when it was begun after the

fifth day in bacteremic cases. The death rate among the seventy-nine patients treated with serum who had type VII pneumonia was 12 per cent as compared with 29 per cent among 160 earlier and contemporary patients not given serum. Type VII cases were more frequently atypical and, because this type is relatively frequent in sputum or in pharyngeal cultures of patients without pneumonia, caution is required in the choice of proper cases for specific treatment. Concentrated antipneumococcus rabbit serums were used for eleven patients. The data indicate that the rabbit serums are probably as effective as horse serums. More data are necessary to determine any superiority of the one over the other. Too few cases have been treated with sulfanilamide to evaluate the place of this drug in the treatment of pneumococcic pneumonias of types V and VII. Sulfanilamide or similar drugs may prove to be valuable adjuncts to serum treatment, particularly in bacteremic cases in which treatment is begun late in the disease. They may also be useful in cases when only serums of low potency are available. Further studies of their use in adequately controlled cases are desirable.

Retained Cervical Stump.—During a recent clinical and pathologic survey of carcinoma of the cervix occurring in the Gynecological Service of the Johns Hopkins Hospital between 1893 and 1935, Henriksen observed that the incidence of true stump carcinoma following subtotal hysterectomy was really low. In this period of forty-two years, 4,300 uteri were removed subtotally because of myomas and 2,250 for other causes of a benign nature. Only 157 patients returned because of complaints relative to the stump. Of these 157 patients, twenty-six were found to have a primary carcinoma of the stump. This figure would be nearly tripled if those patients were included in whom cancer was found either at the time of hysterectomy or within one year following the surgical intervention. There has been no definite attempt to follow these patients and the data are therefore relative rather than factual. The fact that only 2.4 per cent (157 patients) of the 6,550 patients returned to the hospital with complications referable to the stump, and that of these only twenty-six had cancer, indicates that the incidence of stump cancer is so low as to be of relatively little import. There is no evidence that subtotal hysterectomy predisposes to cancer of the stump or that the residual stump is more susceptible to malignant changes than the cervix of a complete uterus. The author does not feel that the 0.45 per cent incidence is sufficient reason to advise the total operation with its morbidity-mortality rate of from 2 to 5 per cent. With proper preoperative and postoperative treatment of the cervix, total hysterectomy as a prophylactic against cancer of the stump is probably rarely indicated.

Food Habits of Mothers of Congenitally Malformed Children.—Murphy and Bowes obtained dietary facts from 545 mothers who had given birth to malformed children. Questions were planned which might be the means of assembling information about the regular food habits of this group of mothers and the changes they made in their diet during pregnancy. 1. About 35 per cent of these women took no milk during pregnancy. 2. About 20 per cent took 1 quart or more of milk daily. 3. About 20 per cent had two servings daily of leafy vegetables, and only 10 per cent reported having from two to four servings daily of other vegetables. 4. Citrus fruit was taken once daily by 18 per cent, and 13 per cent had about two servings of other fruit daily. 5. About 25 per cent used too much bread and only 17 per cent used whole grain bread regularly or often. 6. Excessive use of coffee, tea or alcoholic beverages was not indicated by the reports given. 7. Approximately 40 per cent of these women had an inadequate diet when pregnant with their malformed offspring. 8. Among the mothers using an inadequate diet, anemia was found twice as frequently as among those using an adequate diet. 9. Anemia in the women who gave birth to congenitally malformed children was found four times as often as in a control series. 10. The present observations offer no proof that an inadequate diet or anemia is a predisposing cause for the occurrence of congenital malformations. However, both characteristics were observed with unusual frequency.

Occupation and Optic Cancer.—Lane presents a report on the relation of occupation to 1,000 cases of cancer of the eye. The cases were equally divided between carcinomas and malignant melanomas. The material was obtained from the records of twenty-two eye clinics in the United States and Canada, four institutions devoted exclusively to the study and treatment of cancer, the private records of many eminent ophthalmologists and from medical services of large industrial plants producing chemicals, oils, carbon products and gas. Every case studied has been verified by biopsy or microscopic section of the tumor. More than 154 different occupations were represented. The following general classification was made: exposure to oils and lubricants, exposure to sunlight, to sunlight and the elements, to sunlight and tar, to sunlight and chemicals or irritants, to chemicals, to coal, pitch and tar, to radioactive substances, to metals and miscellaneous occupations. Not all the occupations showed an increased distribution above that found in the average general cancer rate per thousand cases. Occupations in which workers are exposed to oils and having relation to the automotive field show some increased distribution. Printers, plumbers and steam fitters, who use oils more or less in their work, do not show any such increase. Workers exposed to sunlight, the elements, pitch and tar and chemicals show a large distribution. Especially to be noted is the large number of farmers and of laborers who form 85 per cent of the 155 cases in this group. In the miscellaneous group of patients whose work is more or less sedentary and presents no great occupational hazards there is a rather startling increase, particularly in the domestic and personal service occupations, more than one third of the entire 1,000 patients being housewives. Individually the clerical occupations show no increase but taken as a group they do. Likewise the manufacturing and mechanical industries as a group show considerable increase. A small select group of skilled artisans (exposure to metals), mostly of the male sex, show no individual increase in cancer of the eye, but the group as a whole shows a slight increase. The average age of the 500 patients having ocular carcinoma was 57.15 years. The

average age of those with malignant melanomas (sarcoma) was 48.5 years. There were 201 women among the 500 persons with carcinoma and 214 among the 500 with sarcoma. There is an excess of 170 men; however, five of the seven occupational groups had occupations in which, as a rule, only men are engaged. Much of the material was drawn from large industrial centers, which may possibly account for the predominance in men. The ophthalmologists when taking histories of cancer of the eye should inquire how long a patient has followed his occupation; likewise whether any other occupation was followed previous to the present occupation and if so how long that occupation was pursued. These questions often have an important medicolegal bearing. The exact nature of the duties of the occupation should be noted. Details are of importance in solving the cancer problem. Eye clinics, unfortunately almost without exception, have not been in the habit of following up their tumor cases.

Venereal Lymphogranuloma in Women.—Torpin and his associates made a study of ninety-six consecutive cases of venereal lymphogranuloma in women (only four were white women) and found the cases to fall into four overlapping groups: genital, inguinal, anorectal and urethral syndromes. Various therapeutic measures are recommended. A specific has as yet not been found. Sulfanilamide has proved a valuable adjunct to therapy. It is of value in checking the rectal leukorrhea that is so often attendant on rectal stricture, it aids in the healing of ulcerations and it helps drainage from ischiorectal abscesses, sinus tracts and draining buboes to cease. However, thus far the authors have observed but little effect on the secondary lesions themselves, such as rectal stricture, elephantiasic vulvae or papillary excrescences and growths about the genitalia.

Absorbability of Catgut.—Bates subjected healthy adult dogs to gastro-enterostomy under standard surgical conditions. The gastro-enterostomies and the abdominal wounds were each closed with the suture to be studied, and at intervals of twenty-four hours, four days, one week, two weeks and four weeks the wounds were examined grossly for the state of healing, functioning of the suture, fragments of catgut and peritoneal adhesions. Both the gastro-enterostomy and the abdominal wound in each case were examined microscopically after being blocked in celloidin. Not only were typical wounds provided by making gastro-enterostomies, but also the comparative rates of wound healing in the intestine and in the abdominal wall could be studied. None of the dogs had grossly infected abdominal wounds. 1. Employing chromic catgut, studies with 000 sutures showed filmy omental adhesion at twenty-four hours. Grossly, a beginning self support in the wounds was observed in four days. Fibroblasts had appeared by this time. The catgut demonstrated enough tensile strength to continue functioning for fourteen days in both gastro-enterostomies and abdominal wounds. At the end of twenty-eight days about half of the catgut had disappeared. 2. The size 3 chromic suture was inconstantly associated with adhesions. With it both gastro-enterostomy and abdominal wounds healed at about the same rate. At four days there was no gross healing. Small green masses of necrotic tissue had collected about the knots of catgut. Fibroblasts appeared by this time. At eight days the poorly healed wounds contained frayed suture, having little if any function, and after twenty-eight days half of the catgut was phagocytized. 3. The size 1 chromic suture was associated with inconstant peritoneal adhesions. At four days, fibroblasts began to appear in spots. The suture exhibited appreciable tensile strength up to the fourteenth day, after which swelling and fraying reduced it to uselessness; suture particles were present at the twenty-eighth day. Abdominal wounds and gastro-enterostomies healed at about the same rate. 4. Plain catgut, size 000, produced prompt, severe and persistent gross reaction in both kinds of wounds. At four days the catgut had lost all holding power and repeated eviscerations occurred. By eight days the last microscopic traces of catgut were fast disappearing and only then did fibroblasts begin to appear. The gastro-enterostomies all held, however, through their critical period. 5. Size 3 plain catgut in wounds caused much reaction. At four days there was no gross healing in either type of wound. The suture was weak and swollen, and half of it was gone. By the eighth day fibroblasts appeared and by the fourteenth day the catgut had disappeared. Healing occurred at parallel rates in the two kinds of wounds, and peritoneal adhesions were found in some cases and not in others. 6. The more commonly used size 1 plain catgut in both types of wounds was not greatly different from the larger catgut, except that grossly there was somewhat less reaction. The suture functioned no longer than four days, and frayed strands persisted for two weeks. From the first, a wide zone of round cells hastened phagocytosis. The fibroblasts appeared after eight days. Regardless of the size of the suture employed, plain catgut resulted in slower healing and more irritation than chromic catgut. At any day examined, the histologic sections showed a wider zone of round cell infiltration around the plain catgut than around the chromic catgut. True, the larger the plain suture the greater the reaction around it; but there was as much infiltration around the smallest plain suture as around the largest chromic suture. The smallest amount of tissue reaction, the earliest appearance of fibroblasts and the most rapidly healing wounds occurred when the 000 chromic suture was used. The most violent reaction, the most retarded appearance of fibroblasts and wounds which exhibited edema the longest and healed the worst occurred when size 3 plain catgut was employed.

Iodine Metabolism and Hypothyroidism.—Hinton states that thyroid dysfunction may result either from a lack or from an excess of the substances (tyrosine and iodine) from which thyroxine, the active principle of the gland, is formed. An excess of tyrosine and a diminution of iodine might result in a form of thyroxine containing less iodine than normal, and a type of hyperthyroidism would be produced. If, on the other hand, not enough tyrosine was available to mobilize the iodine, a colloid type of goiter might result or there could be hypothyroidism without thyroid enlargement. Such disturbances could be brought about by intestinal disorders, dietary irregularities, scarcity of iodine in the diet or dysfunction of the tissues normally responsible for oxidizing excess of tyrosine. Either an excess or an abnormal side product of the amino acids would be found in the latter case. The early stages of hypothyroidism produce most bizarre symptoms and for that reason the condition is frequently overlooked. The clinical problem in hypothyroidism is provided by the vague symptoms so commonly attributed to some other organ or organs. One should suspect hypothyroidism when patients present dry skin with falling hair or baldness, apathy, general weakness and nervousness when fatigued, i. e., the fatigue coming on late in the afternoon or early evening. Somnolence and constipation are common complaints. It is at times necessary to treat a patient as hypothyroid, although the metabolism may be reduced only to the lower limits of normal, if one is clinically certain of the diagnosis. The lassitude is more marked on arising in the morning, improves during the middle of the day and returns in the late afternoon or evening. Abdominal pain (more than likely typical of peptic ulcer) is frequently associated with the period of lassitude, as are mental depression and irritability. The periodicity of the pain is lacking. Vomiting is occasionally encountered,

usually when the patient is extremely tired. The hypothyroid patient rarely shows any improvement on an ulcer diet, in spite of ulcer symptoms. Obviously, not all patients suffering from the symptoms of ulcer have definite hypothyroidism. Yet some do, and if one is careful to evaluate the symptoms of hypothyroidism these cases can be diagnosed. A basal metabolism will usually verify the diagnosis. The treatment should consist of thyroxine (1 mg.) intravenously once a week, with 0.065 Gm. of thyroid extract orally twice or three times a day. It is important to continue the thyroxine administration intravenously at weekly intervals over a relatively long period: from eight to ten weeks. This may be governed by the clinical course of the patient. From the clinical results obtained from thyroxine administration it would seem that the therapeutic effects lie in the tyrosine radical of the molecule and not in the iodine content of thyroxine. After the patient is free from symptoms and his metabolic determination is normal, he must be made to realize that this state will not continue unless thyroid medication is taken at intervals over a period of months and perhaps years. Improvement is due to a general stimulation of the metabolic processes. Thyroxine tablets, 1/80 or 1/60 grain (0.0008 or 0.001 Gm.), twice a day may prove beneficial in patients who will not tolerate thyroid by mouth.

Tuberculosis Survey in Florida. A. J. Logie, Jacksonville, Fla.—p. 408.

Tuberculin Desensitization for Tuberculosis.—Willis and Jocz used tuberculin supplemented by surgical collapse in the treatment of fifteen patients who had intractable tuberculosis and who obtained no improvement from prolonged bed rest in a sanatorium. These patients were of low skin sensitivity. They were given tuberculin daily in rather rapidly increasing doses over a period of several months. The smallest dose given was 0.1 cc. of 1:1,000,000 dilution and the largest was 1 cc. of undiluted tuberculin. As a rule the initial dose was 0.1 cc. of 1:10,000 dilution. Doses were increased by 0.1 cc. daily. Old tuberculin and trichloroacetic precipitate tuberculin (TPT) were used interchangeably and each was used in each case. Fourteen of the patients so treated had pulmonary tuberculosis and one had tuberculous epididymitis. The clinical course was characterized by one or more exacerbations, by persistent lack of improvement or by unremitting, slow progression. The patients had had an average of three and one-half years of sanatorium care (from one and one-half to seven years) before tuberculin therapy was instituted, which consisted of daily subcutaneous doses of tuberculin given on a scale of increasing amounts and maintained at the patient's limit of tolerance. The doses did not produce demonstrable focal or general reactions, although local reactions accompanied the full doses. Several of the patients might have weathered the disease without tuberculin. However, despite good sanatorium care and good collapse therapy they were prone to relapse or to be stubbornly unresponsive to treatment. At the beginning of the period of treatment three of the fifteen were temporarily improved over their admission status, in eight the condition was stationary and four were worse. At the end of treatment eight were improved, five showed no change and two were worse. In the "improved" group only those were included in whom x-ray evidence of receding disease could support clinical evidence and in whom tolerance to moderate exercise was clear. These patients remained in the sanatorium an average of seventeen and one-half months after tuberculin treatment. At discharge the condition of one was classified as arrested, of five as apparently arrested, of two as quiescent and of three as improved; two patients died and two remain in the hospital and will die. At present, from three to four years after cessation of treatment, seven have the disease in an arrested form and two apparently arrested; two are unimproved (still in the hospital) and four are dead. The authors emphasize the fact that the study was undertaken solely as an experiment; that they do not recommend the general use of tuberculin therapy; that they believe daily injections of rather rapidly increasing concentration of tuberculin in the chronic, "sluggish" case of pulmonary tuberculosis with low tuberculin sensitivity will lead frequently to distinct improvement, and that, if tuberculin is employed at all, the patient should continue under adequate sanatorium and collapse care. The therapeutic use of tuberculin should never be instituted in place of a sanatorium regimen and collapse therapy but always as supplemental to such a program. Unskilful use of this drug may lead to disaster.

Resistance to Tuberculosis.—In his experimental studies Smithburn found that differences in the survival time of animals occurred according to whether tubercle bacilli were inoculated subcutaneously, intravenously or intracerebrally. With the intracerebral route of inoculation the survival time was shortest and individual variation in survival time was least. Comparable groups of animals inoculated intracerebrally with the same dose of the same suspension of organisms did not exhibit significant differences in mean survival time. Comparable groups of animals inoculated with different doses of the same suspension of organisms did exhibit significant differences in survival time. Comparable groups of animals inoculated with the same doses of organisms differing in virulence also showed significant differences in survival time. From his results the author concludes that resistance, as expressed by survival time following inoculation, may be profoundly affected by the virulence of the organisms, the number of them gaining access to the body and the route by which they enter the body.

Precancerous Dermatosis and Epithelioma.—As a working basis Montgomery limits the term "precancerous dermatosis" to true but infrequent Bowen's precancerous dermatosis, senile keratosis, keratosis resulting from arsenic, tar or radiation and various forms of leukoplakia of the mucous membrane of the mouth and genitalia, including the so-called erythroplasia of Queyrat. He shows that in 20 per cent or more of all these conditions epithelioma develops, usually of squamous cell type and, beginning in situ, is associated with various phenomena of dyskeratosis and keratinization of individual cells simulating

most closely the histologic picture of Bowen's disease. The conditions are all interrelated by their common histologic picture and hence a possible common carcinogenic factor. Precancerous dermatoses are not to be confused with the relatively rare epithelioma in lesions of lupus vulgaris, psoriasis, lichen planus and pseudo-epitheliomatous hyperplasia. In many cases of precancerous dermatosis, histologic transitions between a benign and a malignant process may be seen in the same section. The peculiar or distinctive and predominant histologic feature of epitheliomas in situ with the phenomena of Bowen's disease, together with their relatively long duration as such, without clinical or histologic evidence of malignant invasion, the author believes, justifies the grouping of true Bowen's disease, senile keratosis, keratosis resulting from arsenic, tar and irradiation and in most cases leukoplakia of the mucous membranes under the title "precancerous dermatosis."

"Winter Eczema of the Arms."—During the last three winters Niles encountered several patients with a peculiar eruption which, he believes, has not been previously described. The lesions were limited to the extensor surfaces of the arms and occasionally extended to the forearms and shoulders. They consisted of roughly round and circumscribed dry red scaly patches, varying in size from that of a pea to that of a dime. Itching was marked, moderate or absent and when present followed rather than preceded the appearance of the patches. In all cases the eruption appeared at the onset of cold weather. In some cases there had been a similar eruption during previous winters which did not respond to various types of therapy during the winter but disappeared spontaneously before summer and recurred the following fall. The patients bathed daily and the majority twice a day. In no instance was there a personal or family history of allergy. All the patients were in the third or fourth decade of life. So far the daily use of an ointment originally prescribed by Deeks for mycotic infections, combined with less frequent bathing, use of a superfatted soap and careful drying of the affected areas has resulted in a cure in one or two weeks. The other measures when combined with the use of some other ointment proved ineffective. The lesions were purposely reproduced in a few patients by stopping the use of the ointment and superfatted soap and allowing more frequent bathing without careful drying. This second eruption disappeared rapidly with the same treatment that was used for the original condition.

Laughlen and Ide Tests for Syphilis.—Flood and Mayer checked the Laughlen and the Ide test against the Kline slide precipitation test, the Kahn standard test and a two tube Kolmer complement fixation test. There was absolute and relative agreement of the last three tests, 100 per cent in the series studied. In the nonsyphilitic group the Laughlen and control tests agreed for 307 of 314 specimens, or 97.78 per cent. The Ide test was performed on 257 specimens, with an agreement on 246 specimens, or 95.72 per cent. This indicates that the Laughlen and Ide tests are less specific than the standard test used. In the cases of treated syphilis 507 specimens were used for the Laughlen and 404 specimens for the Ide test. There was agreement on 387 specimens with the Laughlen test and on only 232 specimens with the Ide test. The Kahn, Kline and Kolmer tests remained positive in 108 cases, while the Laughlen test was negative and in 163 cases while the Ide was negative. The Laughlen and the Ide test were positive while the control tests were negative in twelve and nine cases respectively, or 2.37 and 2.23 per cent. Thus it is evident that the Laughlen and Ide tests become negative during treatment sooner than the standard tests. The Laughlen test gave an agreement in fifty-one of fifty-seven cases of untreated early syphilis and failed to detect the disease in six cases in which the control tests gave positive results. The Ide test was less satisfactory, detecting the disease in only eighteen of forty-three cases. Neither the Laughlen nor the Ide test was positive in the cases in which the control tests were negative. Of 147 specimens from patients with untreated late syphilis the Laughlen test agreed on ninety-five. There were forty-eight cases in which the Laughlen reaction was negative and the Kahn, Kline and Kolmer tests positive. In only four cases was the Laughlen reaction positive and the control negative. The Ide test was inferior to the control tests in that agreement was present in only forty of 118 cases. There were seventy-five cases in which the Ide test was negative and the control test positive. The opposite was true in only three cases. The Ide test is satisfactory for the examination of spinal fluid but the Laughlen test grossly fails when the spinal fluid is not concentrated.

Sulfanilamide in Interstitial Keratitis.—Sandler reports a case of relapsing resistant syphilitic interstitial keratitis which responded dramatically to sulfanilamide. The patient was given an intramuscular injection of 5 cc. of prontosil and 10 grains (0.65 Gm.) of sulfanilamide three times daily. In forty-eight hours there was a decided improvement of the conjunctival congestion, photophobia and lacrimation, and in ninety-six hours these symptoms disappeared completely. Up to the time of the report the keratitis has not relapsed.

Influence of Exercise on Cardiac Output.—McGuire and his co-workers determined the effects of exercise on cardiac output, stroke volume, oxygen consumption and arteriovenous oxygen difference of five normal subjects, four patients with compensated cardiac disease and five patients with cardiac decompensation. For the controls the average increase in cardiac output following exercise was 2.07 liters per minute, for patients with compensated heart disease it was 1.21 liters per minute and for patients with decompensation it was 0.75 liter per minute. The work performed was essentially the same for all groups. The average stroke volume of the normal subjects increased 19 cc. per beat after work, for the patients with compensated cardiac disease it was 14 cc. and for the patients with cardiac decompensation the average increase was only 4 cc. No constant change in the arteriovenous oxygen difference following exercise occurred in any of the groups. For the normal subjects the average increase in oxygen consumption with work was 148 cc. per minute; for those with compensated heart disease it was 111 cc. and for patients with cardiac decompensation it was only 92 cc. The pulse rate was accelerated moderately after exercise in the normal subjects and in the patients with decompensation. The data suggest to the authors that in patients with severe cardiac decompensation under the conditions of the experiments the cardiac output is not increased with effort to the same degree as it is in normal persons and that relative inability to increase the cardiac output may have an important bearing on the pathogenesis of congestive heart failure.

Relation of Hyperthyroidism to Hypertension.—In a series of 265 cases which Bisgard studied he observed that hyperthyroidism was associated with true essential hypertension

in approximately 8 per cent and with elevations of the systolic pressure above the physiologic level (above 150 mm. of mercury) in 30 per cent. Following relief of hyperthyroidism he states that there were two types of cases: (1) cases of fixed or established essential hypertension, in which the blood pressure and the course of the vascular disease were not significantly influenced by relief of hyperthyroidism, and (2) cases of latent or labile essential hypertension, in which the blood pressure showed considerable reduction after relief of hyperthyroidism or approached a normal level and maintained this level for a long period. In some cases of the second type the pressure subsequently ascends. In these cases there is excessive response in blood pressure to exercise and to the cold pressor test of Hines and Brown. It is suggested that in these cases hyperthyroidism merely precipitates or exaggerates hypertension which is latent. In both types of cases there is arteriolar disease, differing only in degree. The disease is more advanced in the first type, rendering the vascular bed inadequate for even a normal volume of blood flow. In the second type the disease may be designated as pretensive hypertension, which in time progresses to the condition of the first type.

Constrictive Pericarditis and Circulation.—Stewart and Heuer present the clinical manifestations of nine cases of chronic constrictive pericarditis. Partial pericardiectomy was performed in seven. This syndrome should be considered when there are signs of congestive heart failure in the absence of the usual causes of failure. Three of the patients appear to be "cured," three others are greatly improved and the seventh is convalescing. Studies of the circulation show that this syndrome is associated with a decrease in the cardiac output per minute and per beat, a rise in the venous pressure and a slowing of the velocity of the blood flow. These alterations are related to the obstruction to the flow of blood into the heart, that is to interference with diastolic filling and to the interference with contraction by the thickened, adherent pericardium. With pericardial resection and the subsequent clinical improvement the measurements of the circulation undergo parallel changes toward or to normal. There is parallelism in these cases between the clinical manifestations and the objective measurements of the circulation. The authors recommend surgical intervention.

Huntington's Chorea in Illinois.—While completing an exhaustive study of Huntington's chorea from the genealogic, sociologic, clinical, pathologic and laboratory standpoints, Falstein and Stone found that in Illinois the choreic state hospital population remains more or less constant from year to year. Equal numbers of male and female choreic persons with a positive family history have been admitted to the Elgin State Hospital; for the state of Illinois as a whole there have been more female than male admissions, though the difference is not great. The age incidence so far as onset of symptoms is concerned includes every decade up to the ninth, except the first, with the largest number of cases in the fifth. Anticipation is not a constant characteristic of the disease; on the contrary, it appears to be the exception to the rule and is to be expected usually when neuropathic stocks are interbred. Because of the relatively late onset of the disease, many of the patients are married and the eugenic problem is made more difficult as a result. The nationalities represented by the Elgin and other Illinois state hospital cases include German, English, Scotch, Irish, Slavonic, Scandinavian, Lithuanian, Italian, Jewish and Negro groups, with many mixtures as well. There is a surprising number of Germans. About four times as many patients are admitted from urban districts as from rural. Regular choreic centers have been noted in various counties in the state. Although contributing only from 0.1 to 0.2 per cent of the general state hospital population in Illinois, Huntington's chorea presents a chronic problem from the social and psychiatric points of view, offering no practical prospects of solution at this time.

Slow Epinephrine for Chronic Asthma.—Murphy and Jones used slow epinephrine in the treatment of nine cases of intractable chronic asthma. It was apparently as rapid and efficient for the relief of attacks as is ordinary epinephrine hydrochloride. In the patient with chronic intractable asthma slow epinephrine seems to present certain advantages that are not obtainable from the ordinary solutions of epinephrine. The

advantage is in the reduction of the number of injections required to give relief. This does not mean a reduction in the actual amount of epinephrine required. At times the absolute amount is actually increased. The physical nature of the preparation allows larger doses to be given at a single injection. Because a night's supply can be given at one time, some patients, who otherwise had to arise on the hour and inject themselves, have been able to sleep through an entire night. That this is not a coincidental occurrence is shown by the fact that withdrawal of the slow epinephrine necessitated return to frequent injections of the regular solution.

Neurosurgery. D. Munro, Boston.—p. 380.

Treatment of Type III Pneumonia with Serum and Sulfanilamide.—Finland and Brown used specific serum and sulfanilamide, separately or in combination, in the treatment of fifty-six cases of type III pneumonia. The patients had an acute pulmonary infection with evidence from physical and x-ray examinations of either lobar or atypical (broncho) pneumonia. In each case type III pneumococci were obtained either from blood cultures or from specimens of sputum. The therapeutic serums used were mostly concentrated rabbit serums. They were given intravenously in graded doses. Sulfanilamide was usually given by mouth, but in occasional cases of severe illness it was given subcutaneously in 0.8 per cent solution in physiologic solution of sodium chloride. The usual dose was 8 Gm. during the first eight to twenty-four hours and then from 6 to 8 Gm. daily, given in equal divided doses at intervals of four hours together with the same or half the amount of sodium bicarbonate. The dose was decreased or omitted when definite improvement was evident. The clinical results, when the effect of treatment on the death rate and on the duration of the acute disease is considered, are not impressive. However, they do indicate that one is dealing with two useful therapeutic agents. The appreciably lower death rate in the nonbacteremic cases suggests that blood invasion may have been prevented by treatment in some of them. There were three recoveries from bacteremia. It is possible that two of these patients would have recovered spontaneously, since antibodies developed after the sulfanilamide therapy, but this was not true in the third case. Bacteriologic, immunologic and necropsy observations in some of the fatal cases suggest that both the drug and the antiserum, but particularly the combination of the two, had a marked curative effect on the type III infection. Adequate causes for death, apart from the specific infection, were found in an appreciable number of the fatal cases. While it is yet too soon to draw final conclusions, the circumstances suggest that the combination of specific serum and sulfanilamide is a useful and effective means of combating pneumococcus type III pneumonia.

Rheumatic Fever and Exophthalmos.—Schultz cites literature which shows that rheumatic fever and exophthalmic goiter frequently occur in the same individuals and that the sequence in which the two diseases become manifest varies. In the first of the two cases that the author describes exophthalmic goiter antedated rheumatic fever by seven years; in the second the former condition developed five years after the onset of rheumatic fever. The relationship of exophthalmic goiter to rheumatic fever appears to be more intimate than it is generally thought to be. Long intervals of time may separate the development of the two diseases in the same person. In such instances the latter disease does not act as an incitant of the metabolic disturbance. The frequent association of these two diseases in the same individual may be due to the presence of an underlying constitutional anomaly contributing to the development of the two.

Toxic Goiters in Texas.—Phillips gives an analysis of 514 toxic goiters originating in Texas. They are of the exophthalmic, hyperplastic or toxic adenoma type and represent carefully studied pathologic material resected at operation. The cases are those from the surgical department of one hospital in Bell County observed between 1920 and 1938 and are part of a larger study of goiters of all kinds. The 514 cases were from 135 of the 254 counties in the state. The distribution was so widespread that no particular conclusions are to be drawn as to the existence of a goiter belt in Texas. No relationship is found between the occurrence of these goiters and geologic formations, rivers or recorded iodine content of drinking waters.

Lymphatic Vessels and Cancer.—Gray has developed a new method of injecting lymphatic vessels, using thorium dioxide sol, which allows study of the lymphatic system under various conditions. The method has been applied in twenty cases of operable cancer backed by control experiments on normal tissues and in some cases associated with injection also of the blood vessels. The deductions from these investigations are summarized by him along the same lines as those used in the British Empire Cancer Campaign Reports for 1936 and 1937. 1. The mode of spread of cancer to lymph glands is generally by means of lymphatic emboli of cancer cells carried along in the lymph stream. 2. The results indicate that cancer of its own accord does not generally stimulate new formation of lymphatic vessels except in cases in which there is substantial formation of stroma belonging to the cancer or associated precancerous changes involving the laying down of new connective tissue in relation to epithelium and when lymph glands are interfered with either by the presence within them of cancer deposits or by the abnormal state brought into being in some unknown manner by the presence of a cancer peripherally. Further work is necessary to provide proof for these phenomena, but the evidence obtained points to its being correct. 3. By the foregoing statements the author does not mean to imply that there is any evidence from his work for a lymphotropic theory of cancer. The ordinary effects of cancer in appreciable masses on the local lymphatic vessels are not lymphotropic but purely indifferent mechanical effects, leading ultimately to compression and disappearance of the lymphatic vessels within the interior of a cancer. Lymphatic thrombosis plays a small part in these phenomena. 4. Cancer cells generally do not remain for any length of time within the lumen of a lymphatic vessel; that is, the spread of cancer cells by their growth as cords in the lumens of lymphatics is an unusual phenomenon in cases of operable cancer. When it does occur, such permeation seems to be generally only of microscopic extent. The claim that destruction of permeated lymphatics and their contained cancer cells by thrombotic changes does occur could not be confirmed. 5. Based on anatomy and physiology, it seems that the focal lymph glands will be the first and most likely seat of glandular cancer metastasis. Subsidiary or collateral glands may also be involved, though it is to be expected that this will follow involvement of the ordinary focal lymph glands.

British Medical Journal, London

1: 313-370 (Feb. 18) 1939

Sulfapyridine in Gonococcic Vaginitis.—Brown treated twenty-seven cases of gonococcic vulvovaginitis with sulfapyridine, thirty-one with sulfanilamide and six with another sulfanilamide compound (uleron). All the patients treated were from 3 to 10 years of age. The duration of treatment was cut down to only four days for girls receiving sulfapyridine and to ten days for those receiving sulfanilamide. Perhaps the chief advantage of sulfapyridine is that there is no necessity for local treatment apart from merely swabbing the vulva with one part of acriflavine in 1,000 parts of glycerin for the first two or three days. Improvement is apparent within a few hours in some cases treated with sulfapyridine and always within two or three days for both sulfapyridine and sulfanilamide. Discounting the ten immediate failures treated with the three drugs, there were no relapses in *fifty-four cases* while the children remained in the home. In no case in which the rectal tests were negative at the beginning of treatment did infection occur later in the rectum. One of the patients treated with sulfanilamide showed a wart; otherwise no complications developed. Thirty-four girls remained well for from five to thirteen months, fourteen for from three to nineteen weeks and there were six late relapses.

Weil's Disease in Glasgow Sewer Workers.—Stuart points out that in the last three years in Glasgow three men appear to have died from Weil's disease and a fourth has been ill but has recovered. In the present group of workers six out of a total of thirty-six show evidence of past infection, fully supporting the evidence of Fairley and of Alston and others that leptospiral infection is definitely an occupational risk in sewer workers. Probably it will be found that Weil's disease is only an occupational risk of sewer workers in large cities in which the men actually enter the ducts. In smaller towns the work is mainly on the surface and the risk of infection must be infinitely less. Laboratory diagnosis in the first week of the disease is difficult but should always be attempted, since serum therapy is so valuable at this stage. Prophylaxis in sewer workers is difficult. Adequate vaccination with an efficient antigen will probably be the ultimate *solution*. This is highly successful in protecting experimental animals but is still largely experimental in man.

Treatment of Bronchial Carcinoma with Intrabronchial Radon.—In view of the high percentage of cases of bronchial carcinoma that are unsuitable for radical surgical intervention, it is important to consider the value of other methods of treatment in the relief of symptoms and prolongation of life. Therefore Brock and Cann report their results in twenty-five cases in which the surface application of radon seeds by means of intrabronchial containers was used. In many the benefit that followed was slight or temporary or was obscured by the progress of some other feature of the disease, such as the development of local or distant metastases. For this reason the authors are not making a separate record or analysis of all the cases but have selected six for individual mention, as each of these illustrates some point of importance. In five of these six the average survival after treatment was thirteen and one half months, the longest being twenty-one months. The sixth patient died after several months of a comfortable existence. The definite improvement as a result of the treatment with radon or radium in each of the cases is most striking and instructive and should compel one to continue energetically in developing this form of treatment in selected cases. It seems that the best results of intrabronchial radon therapy are to be expected in cases of squamous cell bronchial growths in elderly men, which are naturally rather slow growing. Intrabronchial radon should not be used in preference to radical surgical intervention in curing a patient who is fit or suitable to undergo an operation.

Repeated Tuberculin Tests.—Forbes studied, in normal subjects, the results of repeated intracutaneous tuberculin tests at intervals of one, two, three, four and six weeks. The results show the almost constant occurrence of supersensitization after the first test when the test is repeated at an interval of less than three weeks. After this early increase, sensitivity tends to decline gradually under the influence of frequent repeated testing. The results, however, are by no means uniform and unexpected variations of sensitivity are common. It is emphasized that, because of the considerable variability of sensitivity in normal subjects as shown by repeated tuberculin tests, great caution must be observed in attempting to relate the results of such tests to the course of the disease in tuberculous patients.

Tetrachlorethylene in Hookworm Disease.—Fernando and his co-workers studied the anthelmintic activity of tetrachlorethylene in 111 patients, ranging in age from 2 to 70 years. The drug was found to be effective against hookworm, a dose of 8 cc. being the most effective. It had a slight action against roundworms. The toxicity of tetrachlorethylene has been studied and no appreciable toxic action was observed on the cardiovascular, respiratory, hepatic and renal organs, even after doses of 8 cc. In a few cases, doses of 6 cc. and more have produced symptoms of giddiness, faintness and weakness, and in one case symptoms of narcosis. These effects were only temporary. Doses of from 4 to 5 cc. may be safely given to adults, and two such treatments at intervals of ten days may be expected to cure even severe cases of ancylostomiasis. Children may be given tetrachlorethylene in doses of from four to five times the age in minims. Tetrachlorethylene, in view of its low toxicity and efficacy, is a valuable drug in the mass treatment of ancylostomiasis.

Functional Disorganization of Kidney in Disease.—According to McCance and Widdowson, renal function tests with inulin on five patients have shown the following during diabetic coma, Addison's disease and chronic nephritis: 1. The creatinine/inulin clearance ratios may be much below 1. 2. The urea/inulin clearance and the urine/plasma urea ratios may be extremely low. 3. Dextrose may be almost absent from the urine when the dextrose in the plasma is more than 550 mg. per hundred cubic centimeters and when inulin is passing freely into the urine. 4. The percentage of urinary sodium and chloride may be low in spite of extremely high plasma values. 5. Other functions of the kidney such as the excretion of ammonia may be unimpaired. The two possible explanations of these results are (1) that they are due to excessive reabsorption by the tubule cells caused by the loss of some normal restraining influence and (2) that the dextrose and chloride results are due to a pronounced fall in the glomerular filtration rate in kidneys with relatively normal tubules.

Suppurative Pneumonitis and Lung Abscess.—Garland and Berridge state that only sixteen cases of suppurative pneumonitis have been seen at a large general hospital in two years. In six cases a cavity was never demonstrated throughout the illness. The series included eleven males and five females. Assuming that oral sepsis is more common in males, it might be argued that this preponderance corroborates the view that dental sepsis is an important etiologic factor. The disease was confined to the right lung in ten cases, and for anatomic reasons septic material finds access easier on that side. Seven cases were associated directly or indirectly with inhalation anesthesia.

In eight cases the suppurative pneumonitis followed acute pneumonia and in the remaining case the origin was uncertain. It appears that something more than mere tissue necrosis is required to produce an abscess in acute pneumonia, and the conception of an area of gray hepatization breaking down into a true abscess is probably incorrect. Every case of pulmonary suppuration must pass through a preceding stage of inflammation. This presuppurative stage, especially in cases of aspiration of septic material, has been termed "pneumonitis." Kerley has observed that this condition may clear up without proceeding to abscess formation. Suppurative pneumonitis is a stage further, when actual pus is present in the lung but not necessarily in the form of a localized abscess. The true pathology and morbid histology of suppurative pneumonitis are not yet known. The authors point out that suppurative pneumonitis is quite distinct from the "simple pneumonitis" described recently by Morton Gill. The x-ray appearances of suppurative pneumonitis are not pathognomonic. It is the demonstration of a fluid level which usually first draws attention to an abscess cavity. Although differential diagnosis from a tuberculous cavity is not usually difficult, the x-ray appearances are sometimes inconclusive. Reliance must then be placed on clinical evidence and especially on the character of the sputum and its bacteriologic content. Similarly, confusion may arise when congenital cystic disease of the lung is complicated by pneumonia. A cavity obscured by pneumonitis or by effusion may sometimes be defined by using a Potter-Bucky diaphragm. Occasionally even in the acute stage of lung abscess physical signs of a cavity are present and are of invaluable diagnostic assistance. Conservative measures were adopted in every case, spontaneous healing was awaited and surgical intervention was avoided as far as possible. In only one case was there cause to regret adherence to medical treatment. A young adult with suppurative pneumonitis was treated by bronchoscopic aspiration of the pus, bronchiectasis developed and recovery has not occurred eighteen months after the onset and in one other patient after twenty-four months. One patient died. Here operation had been regarded as contraindicated, for the patient was suffering from a series of complications following acute intussusception. Operation was also withheld in a middle aged man in poor general health and in this patient bronchiectasis developed. In one case an incision into an area of suppurative pneumonitis revealed merely a lung oozing pus and no definite abscess cavity. Eleven patients recovered completely. However, fibrosis developed in two; one is presumably of a permanent type. It appears that one is on firm ground in advocating operation only when there is x-ray evidence of an abscess cavity. Progressive enlargement of the cavity represents an absolute indication for operative treatment. Operation becomes imperative when the patient's general state is deteriorating or when it is believed that the condition is becoming chronic. An empyema complicating any stage of the disease is, of course, always treated surgically.

Treatment of Gonorrhea with a Sulfanilamide Compound.—Shih and Wen used uleron, a sulfanilamide compound, in the treatment of sixty cases (seven acute and fifty-three subacute or chronic) of gonococcic urethritis in the male. Of the seven patients with acute gonococcic urethritis, six sought treatment during the first week of infection and one during the second. Intracellular gonococci were found in stained smears from the urethral discharge of all the patients, and pus and shreds were present in the urine. Of the fifty-three cases of subacute or chronic gonococcic urethritis, the duration of the disease was less than one month in nine, up to a year in twenty-three and between two and forty years in twenty-one. All these patients had previously been given some form of urinary antiseptic, which had been administered orally, subcutaneously, intravenously or locally. Frank urethral discharge was present in forty-one cases, the gonococcus was demonstrable in fifty, and shreds in the urine were found in the specimens of all the cases. The drug was administered in two or three courses separated by intervals of a week. Each course consisted of 12 Gm. of uleron, which was given in 1 Gm. doses three times a day for four days. If the smear was still positive for gonococci after the first course, a second course was given after an interval of seven days. Even though the smear was negative, usually a second course was given as a measure of caution. In resistant cases a third course was given after another interval of seven days. During the intervals if the urethral discharge was absent or became less profuse the urethra was irrigated every other day with a 1:8,000 or 1:5,000 solution of potassium permanganate. In general, the immediate effects of uleron were as remarkable as those of sulfanilamide. Symptoms disappeared promptly, especially dysuria in the acute cases and urethral discharge in the chronic cases. The stained smears from the fossa navicularis became negative for gonococci in two of the acute cases after from 27 to 36 Gm. of the drug had been taken, and in fifteen of the subacute and chronic cases after only 12 Gm. of the drug had been taken. Rapid subjective improvement was often deceiving. One of the acute cases was pronounced cured, one improved and five were unimproved; of the subacute and chronic, twelve were considered cured, twenty-five improved and sixteen unimproved. The percentages of the cured and improved cases are lower than those reported by other workers, but this may be accounted for by the strict criteria which were adopted in evaluating the results. Comparing these results with those obtained by the use of sulfanilamide, the author is impressed by the fact that the subacute and chronic cases seem to respond more readily than the acute cases and that for subacute and chronic gonococcic urethritis uleron seems to be a better agent than sulfanilamide. None of the cases of chronic gonorrheal

prostatitis were benefited by the drug. In the dosage employed, uleron appeared to be nontoxic and well tolerated. Patients who are treated with this preparation should be kept under careful observation until they are truly cured of the disease.

Roentgen Therapy of Morton's Disease.—Ledoux-Lebard points out that the disorder first described by Morton in 1876 is characterized by a typical plantar pain, which is localized at the fourth metatarsophalangeal articulation. He says that Pollosson of France described it under the term anterior metatarsalgia. This metatarsalgia seems to be familial in some cases, but it cannot be definitely stated whether the disorder is truly hereditary or whether there is only a hereditary anatomic predisposition. The exciting cause is usually a trauma, either continuous, such as the wearing of too narrow footwear, or sudden, such as may occur in the course of a fall during dancing or jumping. The disorder is more frequent in women than in men, for of thirty-nine cases reported in the literature thirty concerned women, and of eleven cases observed by the author nine concerned women. In case of sudden onset, a violent pain is felt in the anterior metatarsal region and usually at the fourth metatarsophalangeal articulation. In most cases the pain remains localized here but occasionally it involves also the second and third but never the first metatarsus. As a rule the disorder is unilateral, the right foot being more frequently involved than the left one. Since objective anatomic signs are absent it is difficult to establish the pathogenesis. The treatment is still undecided, but the author mentions periarticular injections of iodized poppyseed oil, infiltration with procaine hydrochloride according to Leriche's method, the wearing of orthopedic footwear and various surgical operations. He thinks that surgical operations should not be employed until roentgen therapy and the aforementioned injections have been tried. On the basis of his own experiences he regards roentgen therapy as the method of choice. Of the cases in which he used roentgen rays, nine could be observed for a sufficient length of time (more than two years) to permit an estimation of the results; seven of these nine were completely cured and another one was greatly improved; the remaining one was not benefited. The author irradiates the antero-external portion of the plantar surface and centers the rays on the head of the fourth metatarsal bone. He utilizes rays of medium penetration filtered through 5 mm. of aluminum, and he applies them in weekly doses of 200 roentgens for from four to six times. In most cases one series of treatments proved adequate, but in four cases three series had to be applied at intervals of two months.

Renal Function After Operations for Reno-Ureteral Lithiasis.—Gonzalez says that the lesions produced by calculi, once their cause is eliminated by conservative surgery, nearly always show a favorable development and that anatomic as well as functional restitution of the upper urinary apparatus is to be hoped for. It is understood, of course, that the lesions are not grave and that the processes are not infectious or destructive, for such cases exceed the possibilities of conservative surgery. In patients who had undergone conservative operations the author compared the outcome of the pyelographic and functional examinations made at the time of their entrance to the hospital with the outcome of the same tests at the time of their dismissal. In the patients with septic lithiasis with impaired renal function, dilatation and other lesions, no change for the better is observed in the functional condition following the surgical operation. Patients who have been operated on return after a certain time to ask advice regarding disturbances which cannot be attributed to a relapse of the lithiasis but which are the result of the lesions caused by the calculus at the beginning of the disease. This induced the author to examine the renal function at later dates, namely three months after the operation, a year after it and in some cases at later dates. In the course of these functional tests he examined the quantity of urine, the chloride and urea concentrations, the elimination of phenolsulfonphthalein and the sediment. The x-ray examination comprised, in addition to the direct roentgenography of the urinary apparatus, ascending pyelography with a contrast medium or pneumo-ureteropyelography. The author describes the outcome of these tests in seven cases. He found that reno-ureteral lithiasis produces in the different branches of the upper urinary tract anatomic lesions the importance and extension of which depend on three factors: (1) the calculus and its localization, (2) the time that has elapsed and (3) the process of infection. He also cites animal experiments carried out by Hinman and shows that the less damaged the renal parenchyma is the more apt it is to receive the physiologic stimuli which govern the function and the reparation; that the reparation of the lesions is inversely proportional to the time that has elapsed since the changes developed; that in the cases in which one kidney remains healthy this kidney alone is capable of satisfying the demands of reparation. This explains why the lesions of the diseased kidney remain stationary. To be sure, the author recognizes the limitations of animal experiments and in the conclusion he stresses that patients with anatomic and functional lesions do not regain their function after the conservative operations and that the changes tend to increase progressively. He stresses the necessity of a complete anatomic and functional examination of the upper urinary apparatus in order to determine the degree of the changes caused by the reno-ureteral lithiasis. The prognosis must take into account the lesions as well as the time of development. The surgical treatment must be selected in accordance with the diagnosis.

*General Biologic Action of Toad Venom. R. Cornilleau.—p. 340.

Action of Toad Venom.—According to Cornilleau the venoms, particularly those of the cobra, the bee and the toad, have been given considerable attention in recent years. His own studies were made on toad venom. He says that the tonic action of toad venom on the heart, if not actually questioned, has at least been minimized by some authors. In this connection he calls attention to Lutembacher's report in the *Presse médicale* (46:1469 [Oct. 5] 1938; abstr. THE JOURNAL Nov. 26, 1938, p. 2054), in which that author emphasized that toad venom is inferior to digitalin and ouabain. Cornilleau admits that for quick and strong action ouabain is the medicament of choice; however, neither digitalin nor ouabain can be used for continuous treatment, because their prolonged use involves the dangers of accumulation. He thinks that the best treatment combines the different medicaments, using the classic heart tonics at the onset and employing toad venom for the maintenance treatment. It is essential to distinguish between alcoholic and aqueous solution of toad venom. Lutembacher used the alcoholic type and observed nausea; Cornilleau, however, uses the aqueous solution of the toad venom. After citing experiments with solution of toad venom on frogs, cats and mice, he stresses the stimulating effect of toad venom on the glandular secretions. The introduction of the venom into the human organism, he says, brings into play extremely complex biochemical reactions, which operate by way of the sympathetic. At any rate, its polyvalence cannot be doubted and that is why the medication with this substance always effects an improvement in the general condition.

Case of Grave Tuberculous Sepsis. M. Künsch.—p. 254.

Relapses After Pneumothorax Treatment.—Behrens says that statistical reports indicate that the late results of pneumothorax therapy are not entirely satisfactory. Apparent cures, that is, cases in which relapses result, are more frequent than is indicated in the literature. The author describes his observations in five such cases that were observed by him in the course of the last two years. Two were under his control more or less continuously, whereas the other three came under his observation following completion of the pneumothorax therapy and after a relapse had occurred. He shows that these observations indicate how the late results can be improved. He emphasizes that the mere transformation of a cavity into a closed focus is insufficient. Under favorable conditions, that is, in the presence of a small new cavity and a sufficiently long maintenance of the pneumothorax therapy, cure may thus be effected. However, the aim of pneumothorax therapy is the complete cicatrization of the cavity, and this can be effected with some degree of certainty only in cavities with elastic walls, that is, in relatively new lesions (early cavity, elastic round cavity). Tertiary cavities, especially after they have reached a certain size, are unsuitable objects. In practice it is often extremely difficult to estimate the pathogenesis and age of a cavity or of a tuberculous process for which pneumothorax therapy seems indicated. Therefore, if pneumothorax therapy is decided on, all measures must be employed to realize its aim. Incompletely closed foci of caseation may lead to dissemination and exacerbation even in the course of pneumothorax therapy, and this danger becomes greater when the pulmonary collapse subsides; that is, when the pneumothorax is discontinued. The author shows that all detachable adhesions must be severed as early as possible, because only thus will the formation of a vascularized, fibrillar scar tissue become possible and only such tissue represents true cicatrization of a tuberculous cavity. At what stage and with what method the cautery is to be performed and whether this or that strand is to be severed has to be decided by the physician in each case.

*Colon Bacterial Vaccines in Treatment of Infectious Cystitis. M. Patriarca.—p. 583.

Vaccine in Infectious Pyelocystitis.—According to Patriarca the most frequent cause of pyelocystitis is infection with pyogenic bacteria, especially colon bacilli. Several treatments, especially the administration of bacterial vaccines, have been resorted to. The author carried on a comparative study of the results of the administration of bacterial vaccines or methenamine in two groups of patients. The clinical and pathologic conditions were the same for the patients in the two groups. The patients had either bacterial vaccines or methenamine for ten consecutive days during which they had no other treatment. Forty-five patients of one group had polybacterial colon vaccine, which was administered by the intramuscular route. Six patients in the other group had intravenous injections of methenamine in daily doses of 10 cc. of a 40 per cent solution. The results were evaluated by the evolution of the condition as verified by microscopic examination of the urine and the behavior of cultures, which were made before and after completion of the treatment. The author found that: 1. Polybacterial colon vaccines control pyelocystitis more rapidly than the injections of methenamine. In both cases the disease may recur. Recurrences are also controllable by either treatment, with better results from colon vaccines than from methenamine. 2. Control of the infection lasts longer after the administration of colon vaccines than after treatment by methenamine. 3. Polybacterial vaccines are more effective than those prepared with only one variety of colon bacillus. The vaccine is harmless and does not provoke phenomena of intolerance.

Relation Between Regulations of Body Temperature and Metabolism of Carbohydrates. N. Festa.—p. 117.
*Ascorbic Acid in Tumoral Tissues. E. Bartolomucci.—p. 126.

Ascorbic Acid in Tumors.—Bartolomucci made quantitative determinations of ascorbic acid in tumoral and peritumoral tissues in twenty cases. He resorted to Tillmans' (2-6-dichlorophenol-indophenol), Martini-Bonsignore's (methylene blue) and Ferrari-Buogo's (precipitation of sulfydryls) technics. He found that the amount of ascorbic acid in tumoral and peritumoral tissues is increased in relation to normal tissues. Cancerous tissues contain more ascorbic acid than tissues of benign tumors. The smaller the amount of fibrous connective tissue in the stroma of a given tumor the greater the amount of ascorbic acid in the tissues. The amount of ascorbic acid in tumoral and peritumoral tissues starts increasing after infiltration of the tissues has taken place. It is moderate in benign conjunctivomas and greater in cancers, epitheliomas and sarcomas.

*Night Blindness as Symptom of Thyrotoxicoses and of Hepatic Diseases. K.-H. Zaffke.—p. 433.

Night Blindness in Thyrotoxicosis and Hepatic Diseases.—Zaffke points out that night blindness or the impairment of the dark adaptation is a regular symptom of vitamin A deficiency. He measured the dark adaptation by means of the Birch-Hirschfeld apparatus. Examining the dark adaptation in twenty-two patients with disorders of the thyroid, he found that in all typical cases of thyrotoxicosis the adaptation curve is pathologic and indicates night blindness. Since recent investigations have demonstrated that fully developed thyrotoxicosis is accompanied by anatomic impairment of the liver and since it is known that the liver is important for the storage of vitamin A, the author assumes that the night blindness which is observed in thyrotoxicosis is a result of the thyrogenic impairment of the liver. In order to determine whether hepatic lesions as such are accompanied by night blindness that is brought on by deficiency in vitamin A, he tested the dark adaptation in twelve patients with various hepatic disturbances. He found that night blindness differs in severity in various hepatic disorders such as catarrhal icterus, engorged liver, cholecystitis and hepatic cirrhosis. The degree of impairment of the dark adaptation seems to be dependent on the severity of the hepatic impairment. The severest and most characteristic disturbances in the dark adaptation are observed in hepatic cirrhoses. Here the curve is so characteristic that it repre-

sents an important aid in the differential diagnosis of hepatic cirrhosis from other diseases of the liver. To what extent the examination of the dark adaptation represents a functional test of the liver is still under investigation.

*Atabrine in Treatment of Giardiasis (Lambliasis). P. De Muro.—p. 262.

Atabrine in Treatment of Lambliasis.—Following a review of the various therapeutic methods that have been recommended for the treatment of lambliasis, De Muro points out that in 1937 Galli-Valerio suggested the use of atabrine. The excellent results obtained by Galli-Valerio induced De Muro to resort to atabrine in fifteen cases of lambliasis. Eight of the patients had chronic colitis, two had rectitis and five had intestinal, hepatic and biliary symptoms. The mode of administration of atabrine was the same as that which the author employed in patients with malaria; that is, for adults three tablets was the daily dose. This dose was divided into two or three parts, each one of which was administered immediately after meals. The medication was continued for from five to eight days. In two cases the atabrine was administered by intramuscular injection (one ampule containing 0.3 Gm. daily) but, since this mode of administration seemed to be less effective, the author recommends the oral medication. Undesirable secondary effects of the atabrine therapy were observed in only two of the cases. One patient had mild abdominal pains and another one showed yellowish discoloration of the skin and of the scleras. This yellowish discoloration is not the result of impairment of the hepatic cells but rather of the accumulation of acridine in the subcutaneous tissue. In addition to the atabrine the patients were given biliary and pancreatic preparations. The stools of the patients were examined twice a week and duodenal specimens were examined two or three times. In thirteen cases the examination of stools and duodenal contents gave negative results after five days of treatment. In the two cases in which the intramuscular administration was employed the stools were likewise normal but the duodenal specimens were not. The disappearance of the organisms was accompanied by a great improvement in the general condition and by normalization of the stools. The author concludes that, although his material is not sufficiently large to permit a final evaluation, the observations prove that atabrine exerts a parasiticidal action on Giardia intestinalis.

*Correlations Between Vitamins B1 and C. M. Kasahara, Y. Nishizawa and S. Hirao.—p. 246.
*Value of Congo Red Test in Cancer Patients. W. Schröder.—p. 248.

Correlations Between Vitamins B_1 and C.—Kasahara and his associates report studies on animals, which they summarize as follows: 1. The antineuritic action of vitamin B_1 is intensified by the simultaneous administration of vitamin C. 2. The growth promoting factor of vitamin B_1 is influenced by the simultaneous administration of vitamin C. 3. Vitamin B_1 exerts a protective action on scorbutic guinea pigs. The authors conclude from these observations that vitamins B_1 and C are synergistic.

Congo Red Test in Cancer.—Schröder investigated the value and the usefulness of the congo red test as a functional test of the reticulo-endothelial system on fifty patients with cancer. In the individual case, the outcome of the test does not permit reliable prognostic conclusions. Although the storage capacity of the reticulo-endothelial system corresponds on the average to the general condition and to the existing defense powers, it does not furnish more information than does the general appearance of the patient or than can be learned from the other methods of clinical examination. Moreover, the method has a considerable margin of variations and of error. The author reaches the conclusion that although the congo red test has value as a scientific experiment it is of no practical value in the examination of cancer patients.

Serum Sodium Chloride and Venous Thrombosis.—Russo mentions changes in the vascular walls, retardation of the velocity of the blood current and changes in the composition of the blood as the three factors that play a part in the development of spontaneous venous thrombosis. Many investigators ascribe the most important role to changes in the blood and recently it has been suggested that connections exist between thrombosis and dietetic or therapeutic measures, such as low sodium chloride intake and diuretic medicaments. A reduction in the sodium chloride content of the blood has been regarded as a factor that might favor the pathogenesis of thrombosis. This problem of a possible connection between hypochloremia and spontaneous venous thrombosis is of great practical importance, because in disorders in which venous thrombosis is frequent such as in circulatory insufficiencies and in certain disorders of pregnancy, salt-free diets are quite frequently employed. To throw some light on this problem the author studied the sodium chloride content of the serum in forty-four cases of thrombosis. He did not detect hypochloremia in any; the sodium chloride values were not lower than in healthy persons and so he rejects the suggestion that a chloride deficiency of the blood is a causal factor in spontaneous thrombosis. Moreover, a review of cases of hypochloremia and animal experiments on chloride deficiency failed to disclose a tendency to thrombosis. Regarding the effect on the blood of the withdrawal of sodium chloride by a salt-free diet or by diuretics and regarding the influence which withdrawal of sodium chloride has on the inspissation of the blood, on the acceleration of the coagulation and on the pathogenesis of venous thrombosis, the author says that the point of attack of the dehydration procedures is in the tissues and that, in view of the tendency of the blood to maintain its composition unchanged, the sodium chloride and water contents are not greatly modified. Moreover, the sodium chloride content of the blood has slight influence on the viscosity of the blood. The author does not believe that the development of venous thromboses in patients with heart disease is connected with the dehydration procedures. Only in exceptional cases may diuretic measures cause inspissation of the blood and a tendency to thrombosis.

*Early Diagnosis of Congenital Hypothyroidism. F. Linneweh.—p. 228.
Investigations on Vitamin C Content of Cerebrospinal Fluid: Problem of Vitamin C Metabolism During Childhood. J. W. Camerer.—p. 240.

Early Diagnosis of Congenital Hypothyroidism.—Linneweh thinks that the majority of the cases of hypothyroidism that occur during childhood are congenital. In view of the fact that the one or more symptoms of congenital hypothyroidism

can frequently be traced back to the first months of life, it is surprising that the diagnosis of congenital hypothyroidism is made so rarely. This is deplorable because of the importance of early diagnosis and adequate therapy for the later development of persons with congenital hypothyroidism. Hypothyroidism does not show the same characteristic aspects in nurslings as it does in children; either the symptoms are less severe or there are signs which, considered by themselves, do not indicate the hypothyroid origin, although, considered together, they clearly demonstrate a hypofunction of the thyroid. The abortive or monosymptomatic forms (isolated dwarfism, Hirschsprung's disease and so on) are disregarded by the author. It has been observed that the weight at birth is 500 Gm. greater in the children with hypothyroidism than in the other children of the same family; this is probably due to an accumulation of water. Among the first postpartum symptoms of hypothyroidism are cold skin, tendency to constipation and thick tongue. The latter may be so large that it closes the open mouth and makes sucking difficult. The food intake is small because the metabolism is impaired. Intestinal tonus and motility are impaired. Moreover, the stools are less copious than is the case in normal children. The result of these disturbances in the digestive process is the persistent constipation, a symptom which, in young nurslings, is especially surprising. Another manifestation of congenital hypothyroidism is the quiet and apathic behavior of the nursling. Disturbance in growth is another sign of congenital hypothyroidism. Especially noteworthy is the retardation in the growth in length. At the age of 6 months the deficit in length may be 6.5 cm. One of the most characteristic signs of hypothyroidism is the retarded appearance of the nuclei of the carpal cones, but this symptom may lead to the erroneous diagnosis of rickets. As a result of this mistaken diagnosis, valuable time may be lost in unsuccessful vitamin D therapy. In this connection the author points out that nurslings with untreated hypothyroidism never develop rickets but that rickets may develop after the hypothyroidism has been treated. The anemia that is characteristic for hypothyroidism is observable also in nurslings, but it is of mild degree and, in view of the fact that mild anemias are comparatively frequent in nurslings, it is of no diagnostic value for hypothyroidism. Further, the author discusses the metabolic aspects of congenital hypothyroidism. He shows that the basal metabolism is of no value either for the diagnosis or for the control of the glandular therapy in nurslings with hypothyroidism, because of the lack of a comparative value and because of difficulties in method. The cholesterol content of the blood serum of nurslings with hypothyroidism shows a different behavior from that of older children and adults with this disorder. Whereas in children and adults the cholesterol content is increased during hypothyroidism, in nurslings with hypothyroidism it is below normal and rises to normal values during administration of thyroidin. From the observation that the cholesterol content of the blood serum of nurslings with hypothyroidism corresponds to that of the newborn, it is concluded that the physiologic increase in the cholesterol content after birth is a function of the thyroid.

*Dupuytren's Contracture as Example for Concurrent Action of Hereditary and Environmental Factors for Development of Variable Characteristic. K. Deckner.—p. 734.
Predisposition to Convulsion and Genotype. H. Nachtsheim.—p. 791.

Heredity and Environment in Dupuytren's Contracture.—Deckner says that Dupuytren's contracture is an especially suitable example for a study of the variable, hereditary physical characteristics, which become manifest only after completion of individual development. The following are the reasons why it can serve as an example of the concurrent action of hereditary and environmental factors: 1. Dupuytren's contracture develops in the majority of cases only after the subject has passed beyond the developmental years. 2. The hereditary character and the mode of transmission of Dupuytren's contracture have been demonstrated and explained in numerous genealogical trees. The number of manifestations (penetration) varies under dominant transmission. 3. The type of manifestation is subject to great fluctuations. 4. The localization of the disease process on the hands involves the possibility of great differences in the action of external influences, corresponding to the greatly differing exertion of the hands in various occupational groups. Hands are especially exposed to external influences and to accidents of all types. In estimating the historical development of the different theories regarding the pathogenesis of Dupuytren's contracture, the author evaluates hereditary factors, the effect of hyperexertion and trauma, and finally neurogenic influences. Further, he discusses the possible action of metabolic diseases. Giving his attention to the morphologic behavior of Dupuytren's contracture, he takes up the anatomic aspects, the relations to muscular torticollis and to induratio penis plastica and then compares the condition to tumors of the palmar aponeurosis. After reviewing the literature on the frequency and the age of manifestation of Dupuytren's contracture, the author gives his attention to the part played by hereditary and environmental factors in its development, emphasizing that the action of environmental factors, even in cases of severest exertion of the hands, can never have even approximately the importance of the hereditary factors; the latter must be regarded as of decisive significance. Environmental factors increase the number of manifestations only slightly; they may induce an earlier manifestation or, in some unusual cases, they may determine the manifestation entirely. In the final part of his paper the author demonstrates the forensic importance of the problem discussed, particularly in suits regarding compensation. He stresses that Dupuytren's contracture cannot be considered as an occupational disease.

Cardiac Alterations in Hypertensive Disease.—Vayl selected for a microscopic study sixty-one cases in which death resulted from hypertensive disease not complicated by arteriosclerosis or atherosclerosis of the coronary arteries. This series contained (1) a group of fourteen hypertensive patients from 20 to 38 years of age and (2) forty-seven patients from 40 to 68 years of age. A microscopic study with various staining methods was made of portions of the heart, the upper sympathetic plexus, the cervical ganglion of the vagus, the stellar ganglion and the solar, thoracic and lumbar plexuses. Altogether, some 6,000 slides were examined. He concludes that the primary phenomenon in hypertensive disease is the rise of the blood pressure and vascular spasm. The morphologic lesions of the blood vessels and of the parenchyma of the various organs with considerable alterations in the heart follow later. Cardiac alterations consist of lesions of the muscle fibers, the vessels, the interstitial tissue and the nervous apparatus. At the same time one must consider the lesions of the vegetative nervous system concerned in the innervation of the heart. Fatty degeneration of the heart was rather insignificant. The author attaches a great deal of importance to the focal destructive changes in the various muscle fibers (micromyomalacia). These may be multiple and may be localized in portions of the myocardium having a particular functional significance. Occasionally larger areas of destruction of muscle tissue were seen, sometimes accompanied by leukocytic infiltration. Lesions of the blood vessels presented a hypertrophy of the muscle wall with consequent destructive alterations, sclerosis and mild hyalinosis and in alterations of hyperergic character analogous to

the malignant nephrosclerosis of Fahr. In the interstitial tissue mild lymphoid infiltrations were found and insignificant sclerotic alterations as well as alterations of hyperergic character expressed in fibrinoid necrosis of collagenous fibers with a consequent development of hystiocytic granuloma undergoing scar transformation. Alterations of the nervous apparatus of the heart consist of lesions of ganglionic cells and of nerve fibers. The most marked lesions of the vegetative system were observed in the cervical plexuses of the sympathetic trunk, next in the ganglion nodosum of the vagus nerve, in the thoracic and lumbar sympathetic plexuses and in the solar plexus. In some of the cases the alterations in the vegetative nervous plexuses are quite marked and consist of lesions of the ganglion cells, nerve fibers and vessels. The lesions of the vegetative nervous system, once developed, influence the state of the blood pressure and the cardiac activity. The author feels that it would be faulty to look to the myocardium alone as the cause of cardiac failure in hypertensive disease. The cardiac failure involves alterations in the musculature, mesenchyma, vessels, nerve ganglions and conduction apparatus.

Four Lead Electrocardiogram in Angina Pectoris.—Van Nieuwenhuizen and his associates maintain that in order to improve the diagnosis of cardiac defects it is necessary to increase the knowledge of the electrocardiographic method. In this report they call attention to nine typical changes of the electrocardiogram in angina pectoris. Two of these, the Pardee-Q and M shaped and W shaped ventricular complexes, were known before but the other seven are described here for the first time. The Pardee-Q, the "notch at the foot of RS" (positive S), the saddle shaped ST curve and the high T wave are based on a clockwise rotation of the electrical axis. Three hundred and fifty-five tracings, in which the described deviations have been found, were collected from 5,500 four lead electrocardiograms. The Pardee-Q was found in 1 per cent of all the curves. In 84 per cent of the cases, coronary sclerosis could be assumed. In nearly half the cases, cardiac failure was present. Almost half the patients suffered from angina pectoris. The deep Q in lead 3 is an important diagnostic aid. The M or W shaped ventricular complexes were seen ten and sixty-three times, respectively. Coronary sclerosis could be assumed in more than 75 per cent of the cases in which these complexes were present. In the remaining cases myocarditis, thyrotoxicosis and other disorders existed. The W shaped complexes coincided almost always and the M shaped complexes coincided always with myocardial impairment. The "notch at the foot of RS" (the positive S wave), is due in 85 per cent to coronary sclerosis; for the rest it is found in rheumatic heart disease, diphtheria, syphilis and tonsillitis. Thus the positive S indicates a distinct disturbance in the blood supply of the heart muscle. The saddle shaped ST segment, mostly together with a positive S, was found in about 2 per cent of all the curves (102 cases); 34 per cent of the patients with this deviation suffered from angina pectoris and 26 per cent had complaints which could be attributed to cardiac failure. In 64 per cent coronary sclerosis existed, in 80 per cent organic disorders of the heart muscle. In 10 per cent anginous complaints existed which were supposed to be a consequence of hypervagotonia. A saddle shaped ST segment is therefore a serious warning to give the heart muscle and coronary arteries a thorough examination. The abnormally high T wave is based (apart from its occurrence in thyrotoxicosis and mitral stenosis) in more than three fourths of the cases on organic heart disease, half of which is coronary sclerosis. In younger persons, hypervagotonia may be the cause of this phenomenon. Atrioventricular block, bundle branch block, arborization block and atypical bundle branch block (Wilson) are frequently based on coronary sclerosis. In the thoracic lead, deviations are found mostly in aged persons and rarely in young persons. Here again the deviations are (apart from bundle branch block, arborization block and atypical bundle branch block) the following: 1. Types which are similar to the C I type (posterior infarction): in contrast to what is seen in acute thrombosis, ST here runs less high above the iso-electric level. 2. Types which are similar to C II: a rectilinear descending, followed by a short rising part of the ST curve. The latter eventually continued into a positive afterstroke. In contrast with the C II type, a Q wave generally appears here and ST usually takes off almost at the iso-electric level. 3. The coronary sclerosis type: a deep Q, low R, deep negative T wave, perhaps frequently a symptom of an old posterior infarction. 4. The deep Q IV, in older persons, when longitudinal position of the electrical axis and mitral stenosis can be excluded and especially when dilatation of the left ventricle exists. The authors conclude that in patients of every age with real anginal complaints one of the features mentioned is almost always found in the electrocardiogram.

Malignant Weil's Disease.—Sjöberg gives a detailed clinical history of a case of Weil's disease which terminated in death. At an early stage of the illness the clinical course gave reason to suspect Weil's disease. The influenza-like beginning, the gradual onset and then the rapid increase in jaundice, the septic temperature with stupor, hypotension and collapse, and finally the enlarged liver, albuminuria and hematuria, anuria and uremia are all symptoms of Weil's disease with a malignant course. Hyperglycemia, although a rare symptom of Weil's disease, was also found in this case. The author further cites two similar cases of Weil's disease that were observed at his clinic by Holmgren in 1934 and 1935. He stresses the factors which these cases had in common with the case described. The bacterioserologic examination of the patient whose history is reported corroborated the diagnosis. The culture of the blood yielded spirochetes; guinea pigs that were given intraperitoneal injections of the patient's urine showed on necropsy the typical changes of Weil's disease; moreover, the postmortem examination of the patient's liver yielded spirochetes. To be sure the agglutination test was negative, but, considering the early stage of the disease, this does not contradict the diagnosis. The author thinks that, although Weil's disease is not common in Sweden, more cases might be recognized at an early stage if blood cultures were made more often. An early diagnosis is important, particularly if serotherapy is to be employed.

Adrenal Cortex Extract in Thyrotoxicosis.—Richardson says that the idea that preparations of endocrine glands other than the thyroid might be of therapeutic value in exophthalmic goiter is not a new one. From 1921 onward reports have appeared in which clinical and experimental evidence was brought forward in support of the theory that adrenal insufficiency is the underlying factor of thyrotoxicosis. After reviewing some of these reports the author says that, in view of the favorable experimental and doubtful clinical evidence, it was decided to investigate the effect of a preparation of the adrenal cortex. All patients were kept at complete rest in bed for at least ten days prior to the administration of the extract. It was injected at 6 a. m. and 6 p. m. on two successive days in 5 cc. doses at first and, in later cases, in 10 cc. doses, making 40 cc. in all (1 cc. is equivalent to 75 Gm. of dried cortex). The basal metabolic rate estimations were made at 9 a. m. under standard conditions of strict rest while fasting. Seven patients were treated with the extract, with a definite alteration in the basal metabolic rate in six. No significant symptomatic improvement was noted, and the blood pressure and pulse rate were unchanged. It is suggested that adrenal cortex extract has an effect on the basal metabolic rate in thyrotoxicosis but that at the present time such medication has little practical application.

That the Undergraduate College Should Give the Future Doctor

WILLIAM MATHER LEWIS, LL.D.
President Lafayette College
EASTON, PA.

A college president might be expected to come before a group of learned men in a spirit of great humility at a time when the American college is under fire as it is today. Articles are being printed to show that business men do not value college graduates highly. Professional schools are complaining of the recruits who come up to them from these institutions. And one group of educational experts making one of the endless number of surveys under which we suffer in silence has made the profound discovery that students know less when they complete their college course than they did when they began!

However, I do not feel particularly apologetic. If any social organization in the United States does not need to be on the defensive, it is the undergraduate college. True, it has its weaknesses, but what organization does not, and what organization works more tirelessly to eliminate such weaknesses? There is no more misunderstood organization. It must attempt to be all things to all men. Furthermore, the same public which criticizes it most severely forces on it countless thousands of uneducable young men and women who retard its work and lower its standards.

Perhaps the business and industrial leaders who were not keen for college graduates are looking for a lower type of recruits. Perhaps the professional schools which criticize so strongly those who come into them from the undergraduate colleges are in some measure seeking an excuse for their own lack of educational effectiveness. And what about the survey organizations which discover that the student leaving college has acquired nothing of value in his four years of experience because he cannot pass certain examinations as successfully as he did at the beginning of his freshman year? It would be equally logical for a doctor to decide that a patient is malnourished because when he uses a stomach pump on him ten hours after a meal he discovers no undigested food in the patient's stomach. Education is a digestive process. Obviously the average freshman can pass a better examination than the brilliant graduate out of college several years.

Education is more than the acquisition of knowledge. It is the translation of knowledge into wisdom. Any one who from the inside, year after year, watches students come into college uncertain, uncouth, uninterested in the things of the mind, uncertain in character, and who sees the majority of them graduating four years later intellectually alert, mannerly, with well formed characters and well trained bodies, realizes that the undergraduate college is rendering a service of inestimable value to contemporary civilization. The general public makes the mistake of assuming that the college is a vocational institution where tricks of this, that and the other trade may be acquired, and not an institution for the building of those foundations which make for effective membership in society and for the abundant life.

Let us therefore approach this question of what the undergraduate college should give the future doctor with the realization that the doctor must be more than a medical or surgical technician and that if he is to be a true success he must develop those attributes which make his influence on his generation beneficial and constructive.

The ancient Hippocratic Oath which most young men and women repeat on the day of their graduation from medical school proclaims "With purity and with holiness, I will pass my life and practice my art." The ethical standards of the doctor, his general culture, his devotion as a citizen are no less to be considered than his technical ability.

In past days it is probable that too much emphasis has been placed on so-called pre-

Read before the Thirty-Fifth Annual Congress on Medical Education and Licensure, Chicago, Feb. 14, 1939.

medical subjects and too little on development of habits of thought and mental attitudes and on ability to translate knowledge into wisdom.

One criticism of premedical education recently made was that the student is older than he should be when he enters the medical school. Thus, when he has completed his course, taken essential graduate work and served his internship, he has the disadvantage of years. There is some truth in this contention; but if we appreciated what education really is and did not confuse it with schooling, if the importance of the home as an educational institution were realized, this weakness would be overcome. The first five years in the life of an individual are probably the most fateful in his life. It is then that the brain expands most rapidly and every experience registers deeply. Our preschool education is being more and more disregarded and mishandled in the average home. If the proper influence were thrown around the child in those early days, the eight years of elementary schooling could easily be reduced to seven, the four years of secondary schooling to three and, for the best students, the college course to three, a total gain of three years. However, it must not be forgotten that the college must provide the future medical student with the minimum of chemistry, biology and physics; that in addition to these tool subjects there are others that are essential for him to have and which cannot be reduced too greatly if his preparation is to be effective.

THE ORIGINAL IMPULSE

When the student comes to the college and announces himself as a premedical student, great care should be exercised as to his orientation, and as soon as possible it should be determined whether or not he really has the qualifications which should send him into medicine. Some time ago, at Lafayette College, we had sixty students who were looking forward to medicine as a profession. It occurred to us that we did not know a great deal about their background. We therefore called them together to ascertain some essential facts. In the first place we found that twenty-two had decided on the medical profession before they began their high school course, that twenty-eight decided to be doctors while in high school and that only ten had made their decision in college. In other words, for many of them the impulse to be doctors was a hangover from childhood. They had looked forward to being doctors at a time when others of their playmates had thought to be policemen or firemen was the thing. We found that 25 per cent of these young men were sons of physicians, whereas 10 per cent of the prelegal students were sons of lawyers. Whether this indicated that their fathers were urging them into their footsteps to take up an established practice we do not know. In any event we had these students talked to by medical deans; we had them taken through the laboratories and dissecting rooms of medical schools and in other ways we showed them the road which they had to travel for their objectives. As a result, a few changed their course and prepared for other activities

The undergraduate college should guard against too early specialization and the pursuit of ideas which will lead later in life to vocational maladjustment. It seems obvious that the medical profession, because of the great development of scientific knowledge, has suffered from too early and complete specialization. To the layman it appears that too many doctors today look on their patients as cases, not as human beings.

I have named the tool subjects in the college to which the premedical student must pay attention. There is a second group of subjects which are partial tool subjects for the physician. Certainly he should have a fine foundation in psychology, which will give him a helpful approach to the patient. He should have free-hand drawing and, for satisfactory office organization, some knowledge of accounting. Another group of subjects almost equally important for him are literature and the social sciences. Scientific achievement in America is at a new high but culture is near a new low. A physician to have influence in his community, and to be looked up to with respect, must have command of good English and an appreciation of good books, good paintings and good music. These accomplishments lift a man above his environment and give the doctor needed serenity and poise. Certainly from the pursuit of general history he can learn much of the progress of medicine and of the effect of health conditions on civilization during the centuries That college which has the proper system of physical education, where all the students through remedial classes and organized games are built up scientifically, has an asset of the highest value in a work which is both physically and nervously exacting.

The lack of refined manners is proving a handicap to many men technically efficient. Beyond the curriculum subjects the undergraduate college should give the premedical student training in manners.

Talking with a head of a New York hospital board not long ago, I learned that 200 men had applied for internship there, of whom nine were to be chosen. After ascertaining the professional knowledge and looking over the personal elements in the candidates they made the final

choice on ascertaining what books and music and plays these men enjoyed. Not only did such an examination prove the breadth of culture but it also suggested an emotional stability which is not the possession of those who find their recreation in exciting and enervating entertainment of different kinds.

Briefly, what the medical schools should receive from the undergraduate colleges is men and women with a limited amount of preprofessional training but with broad culture, good physiques and nervous systems, and the proper character to uphold the ethics of the profession.

Medical History In the Undergraduate Curriculum

WILLIAM G. LEAMAN, M.D.
Assistant Professor of Medicine,
Woman's Medical College
of Pennsylvania
PHILADELPHIA

Thomas Jefferson, early in the nineteenth century, recognized the value of a knowledge of medical history and advised[1] that it be included in the list of fundamental sciences considered essential in the training of the medical practitioner of his day. It was not, however, until the present century that any sustained interest was shown in the subject. During the past few years the number of publications dealing with this cultural aspect of medicine has increased. All but seven of the eighty-four schools in the Association of American Medical Colleges now offer some form of instruction in medical history to the undergraduate.[2] While there is little variation in the manner of presentation of other subjects in the medical curriculum through the use of lecture and laboratory, little uniformity has been noted in the arrangement of the course covering the history of medicine. For this reason the many undergraduates continued to regard one of the most valuable and stimulating fields of study with indifference.

Another important factor behind the lack of popularity of medical history in some medical schools is undoubtedly the manner in which it is presented. Reviewing the subject in a series of lectures in which dates and events are read in chronologic sequence by the faculty member delegated to the task fails invariably to arouse the slightest spark of interest among students. The opinion is taken away with the first lecture that medical history is indeed dry. Rows of empty benches are soon evident. Other schools have entrusted the series of lectures to more stimulating members of the faculty, who have succeeded in organizing adequate courses of instruction in this field. They have proved that much can be gained by delving into the facts of the past. Medical history in their hands has been shown to be more than a pleasant by-path apart from the main road of student travel. A leading example may be found at Johns Hopkins University School of Medicine, where systematic instruction extends over the four years of the curriculum. This well rounded course of study is duplicated in few universities of the world. Its value, in time, cannot fail to be reflected in the attitude, the ethics, the writings, the conversations and the adaptability to social changes; in short, the general culture of the graduate. One has only to compare a modern student heavily burdened with a host of unrelated facts, biochemical, anatomic, physiologic or clinical, to one whose scientific thoughts are well saturated with the historical spirit to detect at once the difference.

In the organization of a suitable course in medical history, many points must be taken into consideration. Most important is the selection of the person from the faculty to give the course. On this hinges success or failure. Eminent scholars of medical history are seldom obtainable except on rare occasions for single lectures. Consequently the assignment goes to the member of the teaching staff who has shown more than the ordinary interest in medical history. The bulk of his time, however, continues to be taken up by the teaching and the practice of his own specialty. Medical history must remain an avocation with opportunities for research sharply limited.

Efforts should at first be confined to a preparation of material for the lectures. If he realizes his limitations and handles the subject with enthusiasm, success will be assured. When success comes, it is essential for the instructor to remain on the ground floor in his relationship to his new subject. In other words, he must realize that, whatever fame he may have acquired as a physician or surgeon, he is still an amateur medical historian. If he must write in his spare hours, he should exercise great care in the selection of his topics.[3] Later I will touch on a method that I have used to improve

Read before the Section on Medical History, College of Physicians, Philadelphia, March 13, 1939.

1. Burwell, Sidney: History of Medicine: Its Introduction into General Medical Curriculum, South. M. J. 25:427-430 (April) 1932.

2. Kiser, E. F.: A Method of Examination in the History of Medicine, J. A. Am. M. Coll. 14:115 (March) 1939.

3. Sigerist, H. E.: Bull. Inst. Hist. Med. 4:2, 1936.

the course for the student, at the same time safely satisfying this urge for medical historical investigation.

In the beginning of the course of instruction in this field, the fact will soon be evident that few medical students retain from high school or college enough knowledge of history to form a suitable background. Relationships between medical and other sciences must be pointed out. The student should be made to realize that the history of medicine is but a part of civilization as a whole and that it cannot be understood fully unless some knowledge is obtained of the social, cultural, political and economic backgrounds of the different periods studied. The method of acquiring historical knowledge should be stressed [4] and the student should be stimulated to investigate suggested topics. Increasing familiarity with libraries will result, and this in turn will aid in establishing a method of research of great value in later years. At all times the student must realize the direct application of a knowledge of medical history to the many problems of practice of the future.

A UNIFYING FACTOR

How to use the time allotted to medical history most advantageously is another problem of organization. Sigerist [5] believes that the minimum of time needed to cover the entire field, even in outline, is twelve hours. However, a shorter course may be possible and prove satisfactory if cooperation is obtained from other departments and the structural framework is supplemented when the opportunity presents itself. Medical history should act as one of the unifying factors in the school; for, after all, it is just as important to the biochemist, the anatomist, the physiologist and the pathologist as it is to the physician and surgeon and other clinical teachers. For, as Sudhoff states,[6] "only an ophthalmologist could write a history of his specialty that would be really worthy of the name. Only a surgeon could write a history of surgery that could be taken seriously. A suggestive and stimulating history of disease can only be written by a practitioner who is thoroughly familiar with its manifestations at the bedside." In other words, a faculty member who possesses the qualifications to teach any specialty in a medical school should be able to cooperate with the medical historian by outlining for the student in an interesting manner the history of his specialty.

In the department of medicine countless opportunities will arise on ward walks with small sections of students to dwell for a short time on the lives and the classic descriptions of disease of pioneer investigators. The newer medical textbooks have small historical sections that make the task easier. Major's recent work,[7] now in its second edition, is an excellent guide to the teacher using this method in the wards.

During the past six years at the Woman's Medical College of Pennsylvania I have given a series of lectures on the history of medicine to the second year class, comprising the first seven weeks of a course listed in the college catalogue as "Introductory Medicine." These lectures represent the first contact that the student has with the department of medicine. I believe that the best introduction to medical science (or any science) is a brief outline of the history of its development. In this short period of seven weeks, one can paint the main trends in medicine's development only in broad strokes. Few digressions from the main stream of progress are possible, but I do call attention to the many tributaries in which much pleasant sailing is possible. The following arrangement of the lectures has been adhered to since the course was begun:

Lecture 1. The Beginning: Prehistoric Medicine; Egyptian Medicine.
Lecture 2. Medicine in Ancient Greece and Rome.
Lecture 3. Medieval Medicine.
Lecture 4. Medicine in the Renaissance.
Lecture 5. The Seventeenth Century.
Lecture 6. Medicine in the Eighteenth and Nineteenth Centuries.
Lecture 7. Medicine in America.

I have recently found the syllabus published by Sigerist [5] most useful. The book list for student reading here given is carefully selected and up to date and I have used it as it stands.

Since the classes at the Woman's Medical College of Pennsylvania are small, it has proved most convenient to divide the hour into three parts: The first part, consisting of one half hour, is given over to the formal lecture. During the next fifteen minutes lantern slides are shown; these include prints, manuscripts, photographs and the like from the usual sources. During the final fifteen minutes, books related to the subject of the day are discussed. In some instances, when available, the first editions are shown. Reprints and more recent popular treatises on the subject are exhibited to familiarize the student with the book. By-ways of investigation are pointed out and questions are answered pertaining to the lecture.

A method of examination in medical history has recently been proposed.[2] A written examination of any kind, including a compulsory thesis, would defeat the purpose of the course as outlined in this presentation. The ones engaged in the teaching of medical history are attempting to add something to the undergraduate's equipment other than dates, facts or

4. Nevins, Allan: The Gateway to History, New York, Appleton-Century, 1938.

7. Major, R. H.: Classic Descriptions of Disease, ed. 2, Springfield, Ill., Charles C. Thomas, Publisher, 1938.

formulas that can be committed to memory for a brief space and then forgotten. The seed when planted needs time to grow. The extent of this growth in the short span of time to graduation eludes detection by any type of written examination or compulsory thesis. If proof is needed of the value of the course, it may perhaps be sought in the manner of approach to some of the questions in the final examination in medicine, if this is oral. Certainly the time allotted to medical history in most medical schools is already too meager to warrant the use of any fraction of it for any type of examination.

During the last few years one can detect an increasing interest in the course on medical history as it has been outlined here, and for that reason I have sought to relieve the monotony of the slides by the insertion, in selected places, of short motion picture films. With the aid of a local amateur theatrical company, acted scenes from the lives of historic and well known medical characters were attempted. I have used films as part of the teaching equipment during the last four years.

The addition of these scenes to the lectures stimulated interest in the course. Even with the hour shifted to 8 a. m. during the past two years, attendance has been close to 100 per cent. Therefore I believe that the films have served their purpose well. In addition, I believe that they have been of inestimable value to the subject matter of medical history in affording a means of harmlessly spending one's enthusiasm. If I have stimulated by this means even a few students to continued investigation in the field of medical history, I am satisfied, for no one knows where that will lead.

Comments and Reviews

FORMAL EDUCATION OF EMINENT MEN

Many investigators assert that the highly educated man is the average rather than the exception among persons of great historical importance. Prof. Mapheus Smith [1] of the University of Kansas has reviewed the evidence in an article concerned with formal education in the lower and higher schools. Reliable information on 29,389 persons reporting their educational background was found in Who's Who in America for 1934-1935, of whom 74.7 per cent were graduated from higher educational institutions, 86.5 per cent had attended such institutions, and 92.8 per cent had attended high schools or their equivalent. From the same source were found data over a long period of years showing the trends in educational experience of eminent persons. The significant fact brought out in the tabulations was the rapid increase in the proportion of college graduates since 1916. Before that time the proportion of college graduates had varied between 57.4 per cent and 61.4 per cent. Throughout the period of thirty-five years, college nongraduates varied within limits of 15.5 and 11.6 per cent. The proportion who had no more than secondary education rose consistently from 1899 to 1910 and then steadily declined after 1916. The proportion of those who were self educated rose to a peak in 1910 and declined to the lowest point in 1928. Nearing's study of 2,000 persons listed in Who's Who in America, 1914-1915, considered representative of the younger generation of American genius, revealed that 77.4 per cent had a four year college education, 86.9 per cent had attended college, and only 13.1 per cent had no college education. There is little difference between Nearing's figure for those who attended college for at least a short time (86.9 per cent) and the figure for the total number of persons in Who's Who in America for 1934-1935 (86.5 per cent).

In the first edition (1934-1935) of America's Young Men is a list of important men, most of whom are under 40 years of age; 95.2 per cent of them had attended college and 86.9 per cent were college graduates; in the second edition of this biennial list, 97.3 per cent had attended college and 88.3 per cent were college graduates. In view of the fact that the percentage of younger leaders with college education found by Nearing in 1914-1915 was almost identical with that for all leaders twenty years later, Smith predicts that the Who's Who in America group in 1954-1955 will be almost entirely from a college background.

In the interpretation of these data, one must take into account the general increase in college education in the United States, which was from 687 male college graduates per hundred thousand males 22 years of age and over in 1880 to 1,137 in 1920, an increase of more than 65 per cent. This figure is greater than the increase in the percentage of persons listed in Who's Who in America with a college education. The national trend toward more education partially explains the trend toward more formal education for prominent men in the present generation.

PROMINENT WOMEN

There is evidence indicating that a somewhat smaller percentage of prominent women are college trained than is true of men. Of 1,622

1. Smith, Mapheus: The General Formal Education of Eminent Men, Scient. Monthly 46:551 (June) 1938.

women listed recently in Who's Who in America, only 52 per cent of those on whom sufficient data were given were graduated from colleges and universities or their equivalents. Another 19.1 per cent attended college without graduating, making a total of 71.2 per cent with some college education, compared with 74.7 per cent graduates and 86.5 per cent with some college training in the total Who's Who in American group. American women, Smith writes, appear to exhibit an inverse relationship between degree of recognition and degree of education. In view of the change in educational background for the total Who's Who in America group in thirty-five years, it seems likely that the difference between the educational background of women of different levels of recognition will be transitory and is largely due to age. In Who's Who in America (1901-1902) only 15.5 per cent of women listed had graduated from colleges and universities, compared with 59.1 per cent for the total group. In 1903 the figures were 23.8 per cent for women and 56 per cent for the total, and in 1934 they were 52 per cent for women and 74.7 per cent for the total. The upward trend for women has been pronounced except in the 1934-1935 period. The present difference between the sexes is not great and probably reflects the differential education of the sexes at the present time.

Some students of the subject have placed the chances for eminence of men with college education at more than a hundred times as good as those who did not have a college education. College education has been extended to increasing numbers of people who, because of the large numbers in relation to the positions of the highest social importance, cannot hope to be entered in the list of the most prominent persons unless that list is broadened. The trend signifies, it is said, that college education does not mean as much for eminence as it once did in this country, unless the definition of eminence is extended to more people.

THE TRENDS ARE CLEARCUT

From his analysis, Smith arrives at the conclusion that the trends toward more advanced education and away from lower limits of education and from self education are clearcut; also that at present there is only a small sex difference in the education of persons in Who's Who in America. A man with college education has many more chances for eminence than one whose education is not extended beyond the lower level. There are, however, many persons still doubtful whether education is responsible in any way for eminence. They say that persons who receive a formal college education have certain qualities of mental capacity and personality which are important in reaching eminence, as well as the opportunity to go to college. Those who would most likely become eminent because of qualities not due to education per se are the persons who are most likely to obtain a formal education.

Education in schools has not been necessary for the development of most of the greatest men of any historical period, if by greatest is meant the foremost ten or twenty. The things that make education formal may have had nothing whatever to do with the result.

Education, however, seems to do in a shorter length of time and more uniformly some things of unquestionable importance. It provides opportunities for contacts with experts along a certain line, experts with whom the potential man of achievement might only with difficulty come in contact outside the university. The time required to obtain the fundamentals of subjects is shortened by the organization of the curriculum. College gives more leisure for study than can be obtained in almost any other way for large numbers of people. It provides companions in study, opportunities for discussions and the joint solution of difficulties; then entrée to leading persons in certain fields is gained through universities through contact with lesser persons. Education adds to one's prestige, so that one makes progress faster. Nevertheless, such a fortunate situation is difficult to obtain.

Self education is still possible in extreme instances, as is education within the family as a first step to achievement along many lines. With the advancement of specialization, such opportunities decrease until it is possible that even the most favorable circumstances outside college will fail to produce a great scientist or other types of leaders. Formal education is more important today in many fields than formerly, and it has not reached the limit of development.

BENJAMIN FRANKLIN

Abridgment of an article by Dr. Robert D. Wright, assistant surgeon, U. S. Public Health Service, published in the *Health Officer*, February 1939.

A recent biography of Franklin by Carl Van Doren creates a new interest in this first American scientist, who to many is not known as a pioneer in medical knowledge. Benjamin Franklin was not a physician but his contributions to medicine were greater than those of many of his contemporaries who claimed the title. The profession may claim Franklin, for he was a member of the Royal Medical Society of Paris, an honorary member of the Medical Society of London, and he held membership in several medical societies in the United States.

Franklin approached medicine as he did everything—with a searching curiosity. His contributions were presented with a disarming naturalness, as if what he explained was too

obvious not to be already known. Hardly a field of medical knowledge escaped the interest of his insatiable curiosity. His medical ideas diluted by a thousand other interests and presented without pomp or attempt at effect lie buried beneath his greatness as a philosopher and statesman.

RAISING FUNDS

Franklin helped found the first hospital and the first medical school in America. The method of raising funds for America's first hospital devised by Franklin has been copied by many hospitals and other agencies to this day. According to his own account:

"I not only subscribed to it myself, but engaged heartily in the design of procuring subscriptions from others. Previously, however, to the solicitation, I endeavored to prepare the minds of the people by writing on the subject in the newspapers, which was my usual custom in such cases. . . .

"The subscriptions afterwards were more free and generous; but beginning to flag, I saw they would be insufficient without some assistance from the Assembly, and therefore proposed to petition for it, which was done. . . .

"This condition carried the bill through; for the members, who had opposed the grant, now conceived they might have the credit of being charitable without the expense, agreed to its passage, and then, in soliciting the subscriptions among the people, we urged the conditional promise of the law as an additional motive to give, since every man's donation would be doubled; thus the clause worked both ways. The subscriptions accordingly soon exceeded the requisite sum, and we claimed and received the public gift, which enabled us to carry the design into execution. A convenient and handsome building was soon erected; the institution has by constant experience been found useful, and flourishes to this day; and I do not remember any of my political manoeuvres, the success of which gave me at the time more pleasure, or wherein, after thinking of it, I more easily excused myself for having made use of cunning."

The medical department of the College of Philadelphia, which had been founded by Franklin, was organized through the labors of Drs. John Morgan and William Shippen in 1766, when systematic lectures were begun in this, the first medical school in the United States.

ARTICLES ON EATING AND DRINKING

Probably Franklin's earliest published observations on medical subjects were his lines on drinking written at the age of 16 and published in the *New England Courant* under the pseudonym of Silence Dogood. He became a vegetarian under the influence of a book by "one Tyron" and learned how to cook his own food in order to carry on this fad. But he left off in a most laughable manner which he can best describe:

"In my first voyage from Boston, being becalm'd off Block Island, our people set about catching cod, and hauled up a good many. Hitherto I had stuck to my resolution of not eating animal food, and on this occasion I consider'd with my master Tyron, the taking every fish as a kind of unprovoked murder, since none of them had or ever could do us any injury that might justify the slaughter. All this seemed very reasonable. But I had formerly been a great lover of fish, and, when this came hot out of the frying-pan, it smelt admirably well. I balanced sometime between principle and inclination, till I recollected that, when the fish were opened I saw smaller fish taken out of their stomachs; then thought I, 'If you eat one another, I don't see why we mayn't eat you.' So I din'd upon cod very heartily, and continued to eat with other people, returning only now and then occasionally to a vegetable diet. So convenient a thing it is to be a reasonable creature, since it enables one to find or make a reason for every thing one has a mind to do."

INTEREST IN HYGIENE

In a time when little was known of hygiene, Franklin was a champion of moderation in eating and drinking, of fresh air, of daily exercising, of frequent bathing.

Interest in fresh air led him to investigate the heating and ventilation of houses. Until Franklin's time smoky chimneys were the rule. One of Franklin's queries for the Junto (that eighteenth century Rotary Club which he founded and kept alive for thirty years) was "How may a smoky chimney be best cured?"

In 1742 Franklin published an essay, "New-Invented Pennsylvania Fire Places," in which he describes the advantages of a new type of cast iron heating apparatus. The "Franklin burner" is still a reality in some American homes, and modern builders are rediscovering a Franklin principle in the construction of living room fireplaces.

John Adams wrote of an incident that occurred in 1776 when circumstances compelled him to bunk with Franklin:

"At Brunswick, but one bed could be procured for Dr. Franklin and me, in a chamber little larger than the bed, without a chimney, and with only one small window. The window was open, and I who was an invalid and afraid of the air of night, shut it close. 'Oh!' says Franklin, 'don't shut the window, we shall be suffocated.' I answered I was afraid of the evening air. Dr. Franklin replied, 'The air within this chamber will soon be, and indeed is now, worse than that without doors. Come,

open the window and come to bed, and I will convince you. I believe you are not acquainted with my theory of colds?' Opening the window, and leaping into bed, I said I had read his letters to Dr. Cooper, in which he had advanced, that nobody ever got cold by going into a cold church or any other cold air, but the theory was so little consistent with my experience, that I thought it a paradox. However, I had so much curiosity to hear his reasons that I would run the risk of a cold. The Dr. then began a harangue upon air and cold, and respiration and perspiration, with which I was so much amused that I soon fell asleep, and left him and his philosophy together, but I believe they were equally sound and insensible within a few minutes after me, for the last words I heard were pronounced as he was more than half asleep. I remember little of the lecture, except that the human body, by respiration and perspiration, destroys a gallon of air in a minute; that two such persons as were now in that chamber, would consume all the air in it in an hour or two; that by breathing over again the matter thrown off by the lungs and the skin, we should imbibe the real cause of colds, not from abroad, but from within."

FRANKLIN AND SMALLPOX

Almost every one contracted smallpox in Franklin's day. The practice of inoculation was introduced into America about 1721 through the interest of Cotton Mather and was first performed by Dr. Boylstone at Boston. Franklin was an apprentice printer on the *New England Courant,* edited by his brother James. The *Courant* opposed inoculation, but Franklin was throughout his life a champion of the practice. He wrote:

"In 1736 I lost one of my sons, a fine boy of four years old, by the smallpox, taken in the common way. I long regretted bitterly, and still regret that I had not given it to him by inoculation. This I mention for the sake of parents who omit that operation on the supposition that they should never forgive themselves if a child died under it, my example showing that regret may be the same either way, and that, therefore, the safer should be chosen."

In 1759 Franklin persuaded Dr. William Heberden of London to write about inoculation as a preventive of smallpox. Franklin wrote a four page preface which is a masterpiece of statistical persuasion:

"About 1753 or 54, the smallpox made its appearance in Boston, New England. It had not spread in the town for many years before, so that there were a great number of the inhabitants to have it. At first, endeavors were used to prevent its spreading, by removing the sick, or guarding the house in which they were; and with the same view Inoculation was forbidden; but when it was found that these endeavors were fruitless, the distemper breaking out in different quarters of the town, and increasing, Inoculation was then permitted.

"Upon this, all that inclined to Inoculation for themselves or families hurried into it precipitately, fearing the infection might otherwise be taken in the common way; the numbers inoculated in every neighborhood spread the infection likewise more speedily among those who did not chuse Inoculation; so that in a few months the distemper went thro' the town, and was extinct; and the trade of the town suffered only a short interruption, compar'd with what had been usual in former times, the country people during the seasons of that sickness fearing all intercourse with the town.

"As the practice of Inoculation always divided people into parties, some contending warmly for it, and others as strongly against it; the latter asserting that the advantages pretended were imaginary, and that the Surgeons, from views of interest, conceel'd or diminish'd the true number of deaths occasion'd by Inoculation, and magnify'd the number of those who died of the smallpox in the common way: It was resolved by the Magistrates of the town, to cause a strict and impartial enquiry to be made by the Constables of each ward, who were to give in their returns upon oath; and that the enquiry might be made more strictly and impartially, some of the partisans for and against the practice were join'd as assistants to the officers, and accompany'd them in their progress through the wards from house to house. Their several returns being received, and summed up together, the numbers turn'd out as follows:

Had the Smallpox In the Common Way of *These* Died			
Whites	Blacks	Whites	Blacks
5,059	485	452	62

Received the Distemper By Inoculation of *These Died*			
Whites	Blacks	Whites	Blacks
1,974	139	23	7

"It appeared by this account that the deaths of persons inoculated, were more in proportion at this time than had been formerly observed, being something more than one in a hundred. The favourers of Inoculation however would not allow that this was owing to any error in the former accounts, but rather to the Inoculating at this time many unfit subjects, partly through the impatience of people who would not wait necessary preparation, lest they should take it in the common way; and partly from the importunity of parents prevailing with the Surgeons against their judgment and advice to inoculate weak children, labouring under other disorders; because the parents could not immediately remove them out of the way of the distemper, and thought they would at least stand a better

chance by being inoculated than in taking the infection as they would probably do, in the common way.

"The Surgeons and physicians were also suddenly oppressed with the great hurry of business, which so hasty and general an Inoculation and spreading of the distemper in the common way must occasion, and probably could not so particularly attend to the circumstances of the patients offered for Inoculation."

LEAD POISONING

Franklin suspected lead as the cause of "Dry Bellyach, with loss of the use of the limbs." In a letter to Benjamin Vaughan, he summarized evidence worthy of a modern textbook:

"The first Thing I remember of this kind was a general Discourse in Boston, when I was a Boy of a Complaint from North Carolina against New England Rum, that it poison'd their People, giving them the Dry Bellyach, with Loss of the Use of their Limbs. The Distilleries being examin'd on the Occasion, it was found that several of them used leaden Still-heads and Worms, and the Physicians were of Opinion, that the Mischief was occasioned by the use of Lead. The Legislature of Massachusetts thereupon pass'd an Act, prohibiting under severe Penalties the Use of such Still-heads and Worms thereafter. Inclos'd I send you a Copy of the Acct. taken from my printed Law-book. . . .

"Being in Derbishire at some of the Furnaces for Smelting of Lead Ore, I was told, that the Smoke of those Furnaces was pernicious to the neighboring Grass and other Vegetables; but I do not recollect to have heard anything of the Effect of such Vegetables eaten by Animals. I may be well to make the Enquiry.

"In America I have often observ'd that on the Roofs of our shingled Houses, where Moss is apt to grow in northern Exposures, if there be any thing on the Roof painted with white lead, such as Balusters, or Frames of dormant Windows, etc., there is constantly a Streak on the Shingles from such Paint down to the Eaves, on which no Moss will grow, but the wood remains, constantly clean and free from it. We seldom drink Rain Water that falls on our Houses; and if we did, perhaps the small quantity of Lead descending from such Paint might not be sufficient to produce any sensible ill Effect on our Bodies. But I have been told of a Case in Europe, I forgot the place, where a whole Family was afflicted with what we call Dry Bellyach, or Colica Pictonum, by drinking Rain Water. It was at a Country-Seat, which, being situated too high to have the Advantage of a Well, was supply'd with Water from a Tank, which received the Water from the leaded Roofs. This had been drunk several Years without Mischief; but some young Trees planted near the House growing up above the Roof, and shedding their leaves upon it, it was suppos'd that an Acid in those Leaves had corroded the Lead they cover'd and furnish'd the Water of that with its baneful Particles and Qualities.

"When I was in Paris with Sir John Pringle in 1767, he visited La Charité, a Hospital particularly famous for the Cure of that Malady, and brought from thence a Pamphlet containing a List of the Names of Persons, specifying their Professions or Trades, who had been cured there. I had the Curiosity to examine that List, and found that all the Patients were of Trades, that, some way or other, use or work with lead, such as Plumbers, Glaziers, Painters, etc., excepting only two kinds, Stonecutters and Soldiers. These I could not reconcile to my Notion, that Lead was the cause of that Disorder. But on my mentioning this Difficulty to a Physician of that Hospital, he inform'd me that the Stonecutters are continually using melted Lead to fix the Ends of Iron Balustrades in Stone; and that the Soldiers had been employ'd by Painters, as labourers, in Grinding of Colours.

"You will see, that the Opinion of this mischievous Effect from Lead is at least above Sixty Years old; and you will observe with Concern how long a useful Truth may be known and exist, before it is generally receiv'd and practis'd on."

NOT A DOCTOR, IN HIS OWN ESTIMATION

Franklin never considered himself a physician. In a letter to his parents, Franklin apologized for meddling in medical matters:

"Honored Father and Mother:

"I apprehend I am too busy in prescribing and meddling in the doctor's sphere, when any of you complain of ails in your letters. But as I always employ a physician myself, when any disorder arises in my family, and submit implicitly to his orders in everything, so I hope you consider my advice, when I give any, only as a mark of my good will, and put no more of it in practice than happens to agree with what your doctor directs."

EXPOSURE OF MESMERISM

Franklin's most memorable medical exploit was his exposure of Mesmerism, a quackery whose financial success is rivaled only by such nostrums as faith healing and "patent medicines." Mesmer came to Paris after being forced to leave Vienna for practicing his fraudulent animal magnetism. Among the gay and idle French nobility of Paris, "the laying on of hands" became a rage. Finally, the king appointed Franklin and four celebrated physicians from the Faculty of Paris to investigate the practice of animal magnetism. Franklin appears to have been the guiding spirit of the investigation. Using the experimental method,

the commission subjected selected patients suffering from a variety of maladies to the action of supposed animal magnetic fluid, with negative results.

SURREPTITIOUS WRITINGS

Franklin seems never to have reached a peace with his passions. He told his illegitimate son, William, "all that was known of whatever excesses there were." The most famous of Franklin's surreptitious writings is his "Advice to a Young Man on the Choice of a Mistress." This famous letter was purchased by the United States government at a cost of $30,000.

"Marriage is the proper remedy. But if you will not take this counsel and persist in thinking a commerce with the fair sex inevitable, then I repeat my former, advice,—in all your amours you should prefer old women to young ones. . . .

"In every animal that walks upright the deficiency of the fluid that fills the muscles appears at the highest part. The face first grows lank and wrinkled, then the neck, then the breasts and arms, the lower parts continuing to the last as plump as ever, so that, covering all above with a basket, and regarding that only which is below the girdle, it is impossible to know of two women an old from a younger. And as in the dark all cats are grey, the pleasure of corporeal enjoyment with an old woman is at least equal and frequently superior, every knack being by practice capable of improvement. But still, I advise you to marry directly."

DISCOVERY OF BIFOCAL LENSES

One of his casual discoveries was bifocal lenses. He wrote:

"I imagine it will be found pretty generally true, that the same Convexity of Glass through which a Man sees clearest and best at the Distance proper for Reading, is not the best for greater Distances. I therefore had formerly two Pair of Spectacles which I shifted occasionally, as in travelling I sometimes read, and often wanted to regard the Prospects. Finding this Change troublesome, and not always sufficiently ready, I had the Glasses cut, and half of each kind associated in the same Circle.

"By this means, as I wear my Spectacles constantly, I have only to move my Eyes up or Down, as I want to see distinctly far or near, the proper Glasses being always ready. This I find more particularly convenient since my being in France, the Glasses that serve me best at Tables to see what I eat, not being the best to see the Faces of those on the other Side of the Table who speak to me; and when's one's Ears are not well accustomed to the Sounds of a Language, a Sight of the Movements in the Features of him that speaks helps to explain, so I understand French better by the help of my Spectacles. . . ."

Franklin died quietly at the age of 84.

NATURE AND THE DOCTOR

Abridgment of the convocation address by Dr. Peyton Rous, delivered at the University of Michigan Medical School, Oct. 1 and published in Science Nov. 25, 1938.

Every good doctor is a naturalist. It is no accident that so many medical students have ranged through the fields as boys for rocks or plants or that John Hunter while at the zenith of his London practice took time to inquire into the structure and economy of whales. To be an ardent observer seems the best of qualifications for the study of medicine.

The three tasks set every human creature, to see, to know and to do, are notably difficult in the case of the physician: he has to perceive disease phenomena, to understand them, and to cure or at least make them tolerable, preventing future instances. The difficulty has been that sick and well alike have forced the doctor to act before he could know and to assume, for practical purposes, that he knew before it was possible for him to perceive. Furthermore, he has had to be infallible: error could have no place in the reckoning. Throughout countless years, people all about the doctor have cried to him "Why don't you do something?" and disease has cried even louder. He has had to do it, to do his ignorant and erring best. This is still his situation as concerns not a few ills. Each case of paralysis agitans, every inoperable cancer that he sees goads him toward action. He must still treat the insane without knowing why they are insane. Yet now at last he has to a large extent worked things round into their proper order and, what is even more important, he sees where next to direct his energies and how to bring them to bear.

This happy state of affairs is essentially recent. He has become a passionately enterprising observer. He invents instruments and technics with complete assurance that they will disclose things worth while, though he may not know what.

The sick have always had more signs and symptoms standing plain to view than the doctor was able to note, even when he had only the outside of the human creature to scrutinize. For generations doctors have been schooled more earnestly in observation than any other large group of men. A keen doctor can still discern new signs and symptoms in diseases long held wholly familiar. It was only yesterday in medical time that those little spots on the inside of the mouth were pointed out which help so much in the recognition of measles. Of late it has become plain that even the doctor has perceived but a small part of the mental workings of healthy man, let alone those of the sick, and that there are reaches of thought far beyond its immediate spectrum. One might have supposed that some of those subtle individuals existing in all ages, to whom guile has been

a pastime and thinking a diversion, would have discovered these reaches and made them familiar. The opportunities were there and the technical means, namely sharp and capable mentalities. The impediment lay in the second of the doctor's tasks, that of interpreting what he saw. Observing seems less necessary when all is sufficiently explained, and what one sees looks different in the light of explanations. He propounded "systems" of medicine (textbooks still flaunt the term) which were so beautifully imagined that they made further search for the causes of disease an impertinence.

THE STUDENT SEES KNOWLEDGE

This effort to explain phenomena before they were fully perceived was not unique with the doctor. It has been the bane of discovery in every field all along. While man is a curious animal, the vice of his curiosity is the ease with which it can be satisfied. Now we try to be dissatisfied with explanations for phenomena not wholly understood, but are we always successful? To the medical student that textbook still seems most worth while which explains best. And he admires those instructors who appear bright and sure in their replies, detesting such as wander uncertainly through the laboratory, qualifying their answer to every question and obviously oppressed with what they do not know. The student sees knowledge as exquisitely sharp and clear because his instructors have not had time to dwell on its blurred outlines and nuances.

This confidence that knowledge is precise cannot last more than a year or two; it is shaken out and away by the facts that buffet the young practitioner from every side. As he goes on with his life he sees the impossible prove real so often that he becomes a humble as well as an ardent observer. The discovery of the roentgen rays may be said to have ushered in a medical era characterized by increasing surprise and humility. It is difficult to realize that only a generation ago men deemed cod liver oil a household remedy perpetuated by superstition and doubted whether sunlight had any virtue beyond the psychic. They then thought of foods wholly in terms of fats, carbohydrates and proteins, mentioning salts, condiments and spices merely for completeness sake, since there were no calories in them and calories were what counted. In that confident period the doctor had suddenly learned so much through his own efforts that he had become mind proud. Now the empirical good has once again made its weight felt and we are again prepared to take hints from the past experience of the race on how to maintain health and to assume there may be reason in them, though we know it not.

In those dark ages of medicine when thinking made things so, there were immense opportunities for the wrong sorts of men, those who had the endowment of visionaries, oftentimes religious. The desire to do good is a magnificent reason for wishing to become a doctor, but it is no sign of fitness. Certainly one would not care to have a great poet or artist as one's physician, no matter how much he knew. For what these see they transmute. A little poet, a minor artist, those who draw their main strength from the sensitive perception of realities, yes, they will do better than well in coping with disease; and there have been many such among good physicians. But the visionary is an unnaturalist; as a doctor he runs amuck. He becomes the most dangerous and effective of all quacks, limpidly sincere and often lovable as a person, carrying his fellow mystics along with him joyfully and dominating ignorant folk through the vigor of his convictions. In the old days the honest mystic had every chance to do the harm of his beliefs. Now he stifles in the atmosphere of medicine, its facts harry him, and he seeks the wide air of occupations in which there are more unconsidered variables.

Nevertheless, as is well known, misbegotten, a priori philosophies explaining all of disease and all its cure are still rife in civilized communities. But now doctors as a class go free of them. It is the laity among whom they make play. Yet a clever new thought affecting the interpretations or treatment of disease will always take strong hold on the doctor. Anybody who scans that microcosm THE JOURNAL for the last thirty years can follow the rise and fall of many an alluring idea. It spreads swift as a contagion, is acclaimed, is utilized everywhere, but at long last begins a lingering disappearance from the literature. Where are the opsonic index, the ninhydrin reaction of yesteryear? The clever idea spreads so fast not only because of the urgency of human need, though this is the prime reason, but because doctors are still school men in some degree, easily governed by ingenious thoughts, rising with enthusiasm to notions that are attractive, and loving to think and work and discuss in company.

Though the doctor can no longer be a metaphysician, much less a mystic, in his interpretation of disease processes, he yet must recognize the force of the mystical point of view. He knows that the mystic has a place and a power in human affairs, that he constitutes a saving opposition to received ideas, leavens the human lump. Yet he realizes also that the mystic cannot be a wise physician.

The third of the doctor's tasks, that of setting things right, is the only one that the public really cares about. Here in all ages there has been the physical devil to pay whenever idea has prevailed over fact. Too often the physician has been unable to see that his triumph of mind over matter was an empty one.

Even when the old doctor was not empowered by rationalization, when they had not made of him a doctrinaire, there yet existed a strong reason why he should persist in a way of treatment that appeared to do harm. Take Benjamin Rush, for example, a hard headed, sensible man. He was at his wit's end to treat yellow fever in Philadelphia in 1793 when he found, while searching for what had been done previously, that a Scotch physician had thought violent purgation to be effective in the Virginia epidemic of 1743. Thenceforth Rush purged and bled with all the energy of a courageous and devoted character. So doing he gave impetus to the American school of bleeders, and they continued to take toll until far into the next century.

THE PARADE OF EFFICIENCY

There was the more reason for the old doctor to hold fast to his ideas, because both his ignorance and the public forced on him the role of seer. The sick have always thought of doctors not as they are but as they would wish them to be. They place trust, they are not prepared to excuse. He has accepted this reliance on him as implicit in his situation, and the result has been not an absurdity but a relationship fine in human values. The doctor has had to be self confident to gain best results. The gold-headed cane of the eighteenth century doctor, his dignity, the ritual formality of his visits to the sickroom, though aiding the patient's state of mind, often trapped him into thinking too well of his own abilities and fenced him in this way from nature. The parade of efficiency in the modern hospital, its cool and silent whiteness, its swiftness in action, the deference to the chief on "rounds," the whole arresting contrast with the outside world, mean more than a task undertaken with the ailing body and release for the patient from responsibility for himself—they imply that things will actually be done with more understanding and more surely than in any other sphere of human effort. But while in this way they help the sick, to no negligible extent they bring risk to the doctor. Their effect on him might be damaging were it not warded off by the disclosures of the clinical laboratory, the x-ray department, the postmortem room, which keep him chastened and effective.

We no longer see disease as disorder, though the term still holds place as a synonym. We perceive that, no matter how abnormal a body state may be, it is still natural. To the scientist even the iridescence of decay, the scum on the pool, are the expression of laws which might be termed wholesome if the word had any meaning in such connection. And with the extension of this view to the public has come a vast relief. For sickness was indeed appalling when it seemed to come out of nowhere and to be obedient to nothing. The special horror of the pestilences was that they walked in darkness. This horror is felt still in relation to a few diseases, notably cancer, but even in these the doctor can perceive laws. To the public yellow fever is now only a virus disease transmitted by mosquitoes, and the plague a bacterial infection. Such knowledge would be fortifying, even if they came again.

The doctor himself has become the complete realist that he has always wanted to be. Facts are his familiars and mold his thought. He still cures in many ways that he does not understand, but now he begins to feel a slight humiliation when so doing. In his primary task of observation he is more than ever behind. Despite all his instruments he is still hampered by sheer inability to perceive, while furthermore the scope of the perseptible has broadened incredibly. It provides one of the greatest of present dangers to the doctor's relations with nature. So much of detail there is for him to look on and realize as to bring risk that at times he may not see the organism as a whole. Yet this is his culminating duty. The wisest physicians will always be general practitioners in the sense that they deal in thought with the whole case.

In the eighteenth century the activities of the doctor as a field naturalist sometimes brought great discovery. Withering was the very man to have been told that a "wise woman" in a nearby village cured dropsy with decoction of herbs. There were more than twenty of them in the mixture, yet, as he remarked, the problem presented no difficulties. Withering, who knew botany, had already produced a compendium of British plants that was to be used for generations after him. Jenner did not have a casual chat with a milkmaid and then take a fling at vaccination. Living in the country and keen about animals of all sorts, his observations convinced him that cowpox and the "grease" in horses represented smallpox in an innocuous form; and after his first successful inoculation he waited nine years, rejecting material after animal material, before he got one that seemed right in his experienced view. With it he made the test which justified publication.

Now as field naturalists we roam chiefly within the body. Bacteriology has supplanted botany, and the habits of organs seem more important than those of animals. It has dawned on us that the happenings in animals and plants have far greater meaning for us than their forms would imply. The same insulin that works in the codfish will save a diabetic man. What takes place within animals and plants is our own vital concern. Nothing in medicine has bettered so much throughout the years as the doctor's relations with nature. Now he is more of a naturalist than ever.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Student Wins State Society Prize

The Iowa State Medical Society awarded its annual Baldridge-Beye Memorial Prize of $100 April 25, during the annual meeting in Des Moines, to Ray E. Trussell, junior student in the State University of Iowa College of Medicine, Iowa City. The prize is given annually by the state society to that student of the State University of Iowa College of Medicine who presents the best thesis on his original investigations. Mr. Trussell's thesis was entitled "Hypersensitivity as a Factor in Chronic Monilia Vaginitis."

A Home for Cook County Interns

The West Side Hospital building, 1850 Harrison Street, has been sold to Cook County and will be remodeled for use as a home for the interns of Cook County Hospital, Chicago, and for the treatment of outpatients. The West Side Hospital was a 165 bed hospital established in 1896. The hospital's license was revoked in June 1938 by the Chicago Board of Health, which, according to newspaper reports, had on several occasions ordered the hospital to renovate the institution and make changes in accordance with the board's recommendations. Although the hospital's license was restored later, the hospital operated on a deficit, and Federal Judge Holly, in March 1939, ordered the trustees of the hospital to begin negotiations for its sale.

Student Awarded Ricketts Prize

The Howard Taylor Ricketts Prize at the University of Chicago has been awarded to George Hartley Jr. for work on the local formation of antivaccinial antibodies by the skin. After inducing macrophages to converge by injecting a substance into the skin, then injecting cowpox virus into this area, Hartley was able to show that antibody capable of neutralizing vaccinia virus appeared before it could be demonstrated in the blood. The practical implications of the experiments hinge on the possibility of building up "local" defenses in the body so that micro-organisms entering the body may be more effectively localized and more quickly destroyed.

The Ricketts Prize was established in 1913 in honor of Dr. Howard Taylor Ricketts, bacteriologist at the University of Chicago, who contracted typhus fever while studying that disease in Mexico and died May 3, 1910. The Ricketts prize is awarded annually on the anniversary of Dr. Ricketts' death to a student in the department of pathology or bacteriology for notable research.

Tenth Anniversary of Premedical Club

The tenth anniversary of the founding of the Pre-Medic Club of the Central Y. M. C. A. College, Chicago, was celebrated Friday evening May 26, in the Lincoln Room, to which students in the medical and dental schools of Chicago were invited. The principal address was given by Dr. Karl A. Meyer, medical superintendent of Cook County Hospital. The activities of this club have consisted of bimonthly meetings, tours of medical interest, yearly exhibits and public health campaigns in the college and the publishing of the *Pre-Medical Journal*. Richard Alpert is chairman of the board of directors for this semester, and David Rumack is president of the club.

Course on Medical Ethics

The school of medicine of Louisiana State University, New Orleans, began a series of lectures on medical ethics March 24, to be continued seven weeks. The first lecture was given by Dr. James T. Nix, dean, Graduate School of Medicine, New Orleans, and his subject was "Personal Relations Between Physician and Patient." Dr. Asahel J. Hockett, superintendent of Touro Infirmary, will discuss hospital administration with particular reference to the introduction of the student to internship. Other lecturers included: Louis J. Bristow, superintendent of the Southern Baptist Hospital, on what the hospital expects of its staff; Dr. George S. Bel, director of the Charity Hospital of Louisiana, New Orleans, on the relation among physicians as set down by codes of ethics, and Dr. Isidore Cohn, professor of surgery at the Graduate School of Medicine, on fee splitting.

These lectures followed a series of lectures on medical economics, which in turn followed lectures on medical jurisprudence, all of which were given for the first time at the school this year.

Evenings of Fine Music

Students and members of the faculty of the University of California Medical School, San Francisco, have enjoyed a series of evenings of fine music at the school from the Holbrook Memorial Phonograph Collection of the University of California. The April concert was devoted to the works of Chopin, and the May to those of Tchaikovsky. The March program included the works of Strauss, Mozart, Verdi, Puccini, von Weber and Wagner.

The Mayo Lecture at Michigan

The annual William J. Mayo Lecture at the University of Michigan Medical School, Ann Arbor, was delivered April 28 by Dr. Harold I. Lillie of the division of otolaryngology of the Mayo Foundation, Rochester, Minn., on the subject "Correlation of the Special Practice of Otolaryngology with the General Practice of Medicine."

The Capps Prize Awarded

The $400 Joseph A. Capps Prize in medical research of the Institute of Medicine of Chicago has been awarded for 1938 to Dr. Broda O. Barnes, who graduated from Rush Medical College, Chicago, in 1937, for his paper on "Observations on the Adrenogenital Syndrome." The prize, founded by the late Dr. Edwin R. LeCount, is awarded annually for the most meritorious investigation in medicine completed by a graduate of a recognized medical school in Chicago within two years after the completion of an internship or of one year of laboratory work.

Internships in the Marine Hospitals

The U. S. Public Health Service desires to receive applications for appointments as second year interns in the marine hospitals operated by the service. Applicants must not be over 30 years old, must have graduated from accredited medical schools and must have completed one year's internship at approved hospitals by next June. Second year internships at marine hospitals are similar to residencies in general hospitals. Appointees will receive a gross pay of $1,800 a year,

from which a deduction of $690 a year will be made if quarters, subsistence and laundry are furnished. Those assigned to the federal penal and correctional institutions will receive $1,620 a year, from which $240 will be deducted if quarters, subsistence and laundry are furnished. It is especially desired to receive applications from candidates who are interested in the service as a career, and appointments will be made with the understanding that opportunity will be afforded to take the next examination for appointment as assistant surgeon. The rank of assistant surgeon corresponds in pay and allowances to that of first lieutenant in the U. S. Army. Those who wish to make application should communicate at once with the Surgeon General, U. S. Public Health Service, Washington, D. C., stating definitely that they are interested in a second year internship and giving the earliest date of their availability.

First Annual Lecture

Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, gave the first annual lecture for the faculty and students of Columbia University College of Physicians and Surgeons, New York, under the auspices of Iota chapter of Nu Sigma Nu April 12. Dr. Fishbein's subject was "The Social Aspects of Modern Medicine."

Regional Convention of Medical Students

The first annual New England Regional Convention of the Association of Medical Students was held at Harvard Medical School, Boston, April 1-3. Dr. Harold E. MacMahon, professor of pathology and bacteriology, Tufts College Medical School, Boston, made the introductory speech; Dr. Hugh Cabot, formerly professor of surgery in the Graduate School, University of Minnesota, discussed "Problems of Medical Care." The following afternoon a symposium on the distribution of medical care was presented by D. V. Brown, Ph.D., assistant professor of industrial relations, Massachusetts Institute of Technology; George Perrott, secretary, Interdepartmental Committee to Coordinate Health and Welfare Activities, and Dr. Elliott P. Joslin, clinical professor of medicine, emeritus, Harvard Medical School. Dr. John P. Peters, professor of medicine, Yale University School of Medicine, addressed the dinner meeting. Clinics arranged for this meeting were held by Dr. Tracy J. Putnam, professor of neurology, Harvard Medical School, on "Dyskinesias," and by Dr. Siegfried J. Thannhauser, associate professor of medicine, Tufts College Medical School, on "Liver Disease."

Student Analysis of the Faculty at Louisiana

An analysis by the staff of the *Tiger*, a student publication, assisted by Elizabeth McFetridge, medical editor, of the educational qualifications of the nearly 200 members of the teaching staff of Louisiana State University School of Medicine shows that graduates of fifty-nine American medical schools and thirteen foreign medical schools and eighty-four American hospitals are represented in the undergraduate training or in teaching experience. Seventy-nine members of the faculty graduated from Tulane University of Louisiana School of Medicine, New Orleans, six from Johns Hopkins University School of Medicine, Baltimore, five each from Rush Medical College, Chicago, and the University of Tennessee College of Medicine, Memphis, and three each from the University of Pennsylvania School of Medicine, Philadelphia, University of Minnesota Medical School, Minneapolis, and the University of Louisville School of Medicine. Forty-six members of the faculty have B.A. degrees, fifty-nine members have B.S. degrees, fifteen have M.A. degrees, and seventeen have Ph.D. degrees.

Intern-Staff Dinner at University Hospital

A dinner meeting attended by interns, assistant residents and staff members of professorial rank of the University Hospital, Ann Arbor, Mich., was held March 21. Some of the senior staff members recalled conditions in the hospitals before regular intern appointments were customary and when senior students assisted physicians by carrying out some of the duties now assigned to the interns. Improvements in intern training and developments in residencies in the specialties were discussed. Some members of the present intern staff were called on for suggestions and criticisms in regard to the intern service. This was a profitable event, and plans are being made for frequent meetings of this sort in the future.

New Department of Medical Economics and Postgraduate Instruction

A new department of medical economics and postgraduate instruction has been created at the Indiana University School of Medicine, Indianapolis. The chairman will be Dr. Cyrus J. Clark, who also will be associate professor of cardiology. The additional personnel of the new department will be as follows:

Dr. Leonard A. Ensminger, professor of orthopedic surgery and assistant in medical economics and postgraduate instruction.

Dr. Louis H. Segar, clinical professor of pediatrics and assistant in medical economics and postgraduate instruction.

Dr. Jacob K. Berman, assistant professor of surgery and assistant in postgraduate instruction.

Dr. Howard B. Mettel, assistant professor of pediatrics and assistant in medical economics and postgraduate instruction.

Dr. John E. Owen, assistant professor of surgery and assistant in medical economics and postgraduate instruction.

Dr. Ernest O. Asher, associate in medicine and assistant in medical economics and postgraduate instruction.

Dr. Kenneth G. Kohlstaedt, associate in medicine and assistant in medical economics and postgraduate instruction.

Dr. Walter P. Morton, associate in genito-urinary surgery and assistant in medical economics and postgraduate instruction.

Dr. William N. Wishard Jr., associate in genito-urinary surgery and assistant in medical economics and postgraduate instruction.

James E. Moffat, Ph.D., professor of economics.

Dr. Thomas S. Cullen Retires as Professor

Dr. Thomas S. Cullen has retired as professor of gynecology at Johns Hopkins University, Baltimore, which position he has held for almost twenty-two years, and will receive the title of professor emeritus. Dr. Cullen was born at Bridgewater, Ont., in 1868 and graduated from the University of Toronto Faculty of Medicine in 1890 as a silver medalist. He served as chairman of the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, 1914-1915, and has been a member of its Board of Trustees since 1929.

Annual Reunion at University of Cincinnati

The Annual Reunion of the College of Medicine of the University of Cincinnati will be held Saturday June 10. Dr. Robert H. Kotte, president of the alumni, and a committee are in charge of the program. At 9:30 a. m. rounds will be made in the surgical service with Dr. Mont R. Reid, in the pediatric service with Dr. A. Graeme Mitchell and in the medical service with Dr. Marion A. Blankenhorn. A banquet will be held at 7 o'clock in the evening at the Netherland Plaza Hotel. The principal speaker will be Dr. Carl A. Wilzbach, commissioner of health of Cincinnati. The 1939 Reunion has been affectionately dedicated to Dr. John C. Oliver. Dean Alfred Friedlander will present the graduating class, the members of which will be inducted into the alumni association.

New Professors at Washington University

Dr. Dalton K. Rose, associate professor of genito-urinary surgery, Washington University School of Medicine, St. Louis, has been made full professor and head of that division in the department of surgery. Dr. Rose was born in 1886 and graduated from Washington University School of Medicine in 1915. Dr. Robert A. Moore, assistant professor of pathology at Cornell University Medical College, New York, has been appointed Edward Mallinckrodt professor of pathology and head of the department at Washington University School of Medicine, St. Louis. Dr. Moore was born in Chicago in 1901 and received his M.D. degree from Ohio State University, Columbus, in 1928.

Gold-Headed Cane Bestowed on Honor Graduate

The University of California Medical School, Berkeley, has revived the custom of "handing down the gold-headed cane" in a special ceremony symbolizing the custom of English physicians of long ago of carrying gold-headed canes, in the hollow heads of which they carried herbs to protect themselves from disease. The medical student thus honored was Warren L. Bostick of San Diego, who was given a gold-headed cane; Warren E. Jones of Sacramento and William R. Rosanoff, Los Angeles, were given copies of the earliest edition of a book by Macmichael describing the cane ceremony and giving the history of its recipients. A new cane is to be presented next year to the honor graduate in the same manner. Dr. Herbert C. Moffitt, clinical professor emeritus, who made the presentation speeches, was also given a gold-headed cane in recognition of fifty years of service with the university. Dr. Moffitt was the honor graduate of the university in the class of 1889.

National Board Questions in Surgery and Public Health

Following are the questions used by the National Board of Medical Examiners in surgery and public health in part two of the examination held Sept. 12-14, 1938:

MEDICINE

Answer questions 1 and 2 and three of the remaining four: 1. What involvement of the nervous system is most commonly associated with pernicious anemia? What are the signs, symptoms and differential diagnostic features? 2. Contrast the physical signs of pneumothorax with those of massive collapse of the lung. 3. What are the signs and symptoms of acute morphine poisoning? Outline the treatment. 4. Discuss the etiology and describe the course of granulocytopenia. 5. Discuss the etiology and diagnosis of abscess of the liver. 6. What is the significance of albuminuria?

PUBLIC HEALTH

Answer four of the following questions: 1. Discuss the etiology, mode of transmission and methods of prevention of trichinosis. 2. What advice should be given to the mothers in a community in which an epidemic of measles is prevalent? 3. Name three virus diseases and discuss the methods of control of one of them. 4. How may a room recently occupied by a patient with scarlet fever be made safe for subsequent occupancy? 5. Name six diseases that may be treated or prevented by the administration of serums, toxins, antitoxins or vaccines. State which one of these substances would be used in each disease mentioned, and describe in detail the procedure of administration in one.

Prize for Qualifications for Successful Physician

An annual prize of $100 has been established by the Zeta chapter of Nu Sigma Nu at Northwestern University Medical School, Chicago, to be awarded on the basis of scholarship, personality and general qualifications for the making of a successful physician. The Committee of Award is composed of Dr. Irving S. Cutter, dean; Dr. Loyal Davis, professor of surgery; Dr. Andrew C. Ivy, professor of physiology and the active president of Zeta chapter of Nu Sigma Nu. In addition to the money prize, the fraternity will place a bronze tablet in the medical school library on which the names of the winners will be inscribed in chronologic order. The first award will be made to a senior of the 1939 graduating class.

Professor Urey to Succeed Professor Sherman

Harold C. Urey, Ph.D., professor of chemistry at Columbia University, New York, has been appointed executive officer of the department of chemistry for a term of three years beginning July 1. He will succeed Henry C. Sherman, Ph.D., who has been head of the department for twenty years and who will now devote his time to research and teaching. Dr. Urey was born in 1893 and received his Ph.D. degree from the University of California in 1923. He was awarded the Willard Gibbs Medal in 1934 for the discovery of "heavy water" and received the Nobel Prize in Chemistry in 1934. He is the author of numerous articles on subjects dealing with the structure of atoms and molecules. Dr. Sherman was born in Virginia in 1875 and received his Ph.D. degree in 1897 from Columbia University. He is the author of many books, the latest being "Chemistry of Food and Nutrition," published in 1937.

Graduate Course in Otolaryngology

A two weeks postgraduate course in otolaryngology at Indiana University School of Medicine, Indianapolis, in April was attended by thirty-four physicians from twenty-two states, some as far away as Maine and California. The course, said to be the only one of its kind in this country, was created mainly through the efforts of Dr. John F. Barnhill seven years ago. The chairman of the course this year was Dr. Carl H. McCaskey.

Dr. Cowie of Michigan Honored

Dr. David Murray Cowie, professor of pediatrics and infectious diseases at the University of Michigan Medical School, Ann Arbor, was honored on his sixty-sixth birthday by the members of the University of Michigan Pediatric and Infectious Disease Society who were present in Ann Arbor for their seventeenth annual meeting. A watch was presented to Dr. Cowie at a dinner given Nov. 11, 1938, by the members of the society as an expression of their appreciation for his inspiration and guidance during the many years that he has had charge of instruction in pediatrics at the university.

California's Premedical Club

Members of the faculty of the University of California Medical School lectured on personal hygiene, mental hygiene, nutrition and physiology to premedical students on the campus of the University of California, Berkeley, May 1. The talks were under the auspices of the Premedical Club.

Virginia Personal

Dr. Patrick H. Drewry Jr. has been appointed assistant professor of neuropsychiatry at the Medical College of Virginia at Richmond. He is now in London studying under a fellowship from the Rockefeller Foundation. He expects to begin his work at the college next spring when the new hospital, which will have an active psychiatric service, will have been completed.

Lectures on Social and Economic Aspects of Medicine

Western Reserve University School of Medicine, Cleveland, offered a series of lectures on the social and economic aspects of medicine, a forum discussion primarily for medical students but open to others interested. The series, presented on Tuesdays and Fridays from March 17 to May 9, was divided into three parts: "A Dynamic Society Encounters Medical Problems," "The Medical Billion and Where It Goes" and "Democracy Feels Its Way." Among the lecturers were:

Dr. Richard A. Bolt, Cleveland, Sickness and Disability as a National Problem, March 17.
Dr. Roscoe D. Leas, Cleveland, Science Advances: Adequate Medical Care Today and Yesterday, March 24.
Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, The American Medical Association Views Health Insurance, April 25.
Mr. H. van Y. Caldwell, executive secretary, Cleveland Academy of Medicine, Voluntary Prepayment Plans for Medical Care in the United States, April 28.
Dr. Ralph C. Williams, Washington, D. C., Group Medical Care for Low Income Farm Families, May 2.
Dr. Sidney M. McCurdy, Columbus, Medico-Social Aspects of Workmen's Compensation.
Charles-Edward A. Winslow, Dr.P.H., New Haven, Conn., Medical Care for the Nation.

Dr. Rogoff Appointed Professor of Endocrinology

Dr. Julius M. Rogoff, recently visiting professor of physiology in the Division of Biological Sciences, University of Chicago, has been appointed professor of endocrinology at the University of Pittsburgh School of Medicine. A special laboratory of experimental endocrinology has been established for Dr. Rogoff's research. Dr. Rogoff graduated in medicine in 1908 at Cleveland College of Physicians and Surgeons, the Medical Department of Ohio Wesleyan University, later merged into Western Reserve University. From 1913 to 1934 he was a member of the faculty of Western Reserve, joining the University of Chicago in 1935 as research associate in physiology. The new laboratory will be supported by the G. N. Stewart Memorial Fund.

Reunion of Presbyterian Hospital Interns

A reunion of former Presbyterian Hospital interns and residents in connection with a two day clinic program for Rush Medical College Alumni will be held June 12 in Chicago. Among those who will take part in the program will be Dr. Russell M. Wilder of the Mayo Clinic, Rochester, Minn.; Dr. Fred M. Smith, head of the department of theory and practice of medicine, University of Iowa, Iowa City; Dr. George M. Curtis, head of the department of research surgery, Ohio State University, Columbus, and Dr. Waltman Walters of the Mayo Clinic.

Annual Lecture at Yale

The first annual lecture for faculty and students at Yale University School of Medicine, New Haven, Conn., under the auspices of the local chapter of Nu Sigma Nu, was delivered April 28 by Dr. Perrin H. Long, associate professor of medicine at Johns Hopkins University, Baltimore, on "The Experimental and Clinical Use of Sulfanilamide, Sulfapyridine and Allied Compounds." Prior to the lecture, a banquet in honor of Dr. Long was given at the "Graduates' Club."

Medical College of Virginia

Mrs. Malcolm Perkins has given $1,000 to the college for a fellowship in immunology and Dr. Edwin D. Vaughan has been appointed to this fellowship for the current year.——Mrs. Annie R. F. Frayser recently gave $2,000 to the college in memory of her son, the late Dr. Benjamin Hobson Frayser, Lexington, Ky., to establish a medical student loan fund.——A grant to the college to provide a resident artist has been made by the Carnegie Corporation of New York. Mr. George H. Murrill has been selected and is now working on murals for the clinic and laboratory building. Murals are also being planned for the library building.

Dr. Graham Honored

A dinner was held at Riley Hospital, Indianapolis, May 8 in honor of Dr. Alois B. Graham, who will retire in June after forty years as a member of the faculty of Indiana University School of Medicine, Indianapolis. The board of trustees of the university presented a gold medal to Dr. Graham. Among the other speakers were the mayor of Indianapolis and the dean of the school of medicine. Dr. Graham is a former president of Marion County Medical Society and of the Indiana State Medical Association and a former chairman of the Section on Gastro-Enterology and Proctology of the American Medical Association.

University of Michigan Health Service

The University of Michigan Health Service celebrated its twenty-fifth completed year of work in a special program recently for which 300 invitations were issued to former staff members and to a selected list of the faculty and friends. In the evening Dr. Harold S. Diehl, dean of the division of medical sciences, University of Minnesota, gave a lecture on "Significance of the Student Health Movement." At the banquet, President Ruthven announced the final arrangements which will provide the health service with a new building designed to provide ample space for an expanded program.

Connecticut Personal

Dr. Stanhope Bayne-Jones, dean of Yale University School of Medicine, New Haven, recently was a guest of the faculty of the School of Tropical Medicine at San Juan, Puerto Rico, where he gave a lecture on "Recent Advances in Cancer Research."

Florida Personal

Dr. Leo C. Gonzales, Jacksonville, director of venereal disease control of the Florida State Board of Health, lectured before Alpha Epsilon Delta, national honorary premedical fraternity, at the University of Florida, Gainesville, recently, on "Methods to Control Venereal Disease in the United States."

Robert J. Terry Lecture

The first Robert J. Terry Lecture was delivered by Dr. Lewis H. Weed, professor of anatomy at Johns Hopkins University School of Medicine, Baltimore, May 17, at the Washington University Medical School, St. Louis. The subject of Dr. Weed's address was "Anatomy in the Medical Curriculum."

Minnesota Personal

Dr. Walter C. Alvarez of the Mayo Clinic, Rochester, Minn., gave the address at the dedication of the new $450,000 building of Hahnemann Medical College, Philadelphia, February 28. On this occasion the honorary degree of doctor of science was conferred on Dr. Alvarez.

Fellowships Awarded

Awards totaling $12,500, including traveling fellowships, scholarships and fellowships, were given to fourteen men for the coming academic year, according to an announcement from Harvard Medical School, Boston, recently.

BURNS IN CHILDREN

A METHOD OF TREATMENT AND ITS RATIONALE

HARRY M. BLACKFIELD, M.D.
AND
LEON GOLDMAN, M.D.
SAN FRANCISCO

The knowledge gained from clinical and experimental observations during recent years has caused us to change our conception of the subject of burns. Not satisfied with all the aspects of existent therapy, we have adopted some and revised other features of prevalent methods in order to combat the manifold effects of an extensive burn. We have combined the tannic acid, silver nitrate and gentian violet methods of local treatment, because this combination complies with our understanding of the subject and, in our opinion, produces the best results in the many children treated for burns at the San Francisco city and county and the University of California hospitals.

Statistics reveal startling facts concerning burns in children. In the United States approximately 40 per cent of all deaths from burns occur in children under 15 years of age, and 75 per cent of these deaths occur in children under 5 years. Stoves, grates, hot water, steam and matches are the chief agencies of injury. In children under 5, scalds head the list of fatal burns, most of them occasioned by the propensity of young children to pull containers of hot liquids from stoves or tables. The fault lies with the adult who negligently permits these agents of death to be placed within the reach of a child.

The mortality from burns as a whole has decreased more than 60 per cent during the past twenty years, as shown in the accompanying table. The actual number of serious burns in homes has declined for various reasons, among them the diminishing use of the coal stove, the replacement of gas burners and oil lamps by electricity and the education of adults by safety workers. The medical profession has done its share in reducing the number of fatalities by the introduction of newer methods for the treatment of burns.

Our experience has convinced us that the prognosis for all burned children should be guarded. We wish to emphasize also that one cannot foretell, from the size of the burn, what degree of toxicity may follow (fig. 1). The chemical equilibrium is so easily disturbed in children, with changes in the volume of the blood and the osmotic pressure resulting from increased capillary permeability, that their narrow reserves may be depleted if not safeguarded early. Shock invariably is present in children with diffuse burns. The necessity for prompt hospitalization of such children therefore is evident.

Not long ago the hypothesis of the absorption of decomposed proteins was upheld by many authorities as the explanation of all the symptoms which occurred during the different phases following burns. As a result of subsequent experimental work, however, it is known that the clinical course of a patient with a severe burn represents a procession of several intermingling phases which cannot be explained on the basis of any one theory.

PRIMARY PHASE: TRAUMATIC SHOCK

In children, burns involving only a small area may be associated with shock, while extensive burns always are followed by this phenomenon. Such shock presents the identical clinical picture of traumatic or surgical shock and is characterized by loss of body heat, cold moist skin, rapid pulse and fall in blood pressure. This phase usually is transient but may be prolonged or even become fatal if not recognized and treated properly.

SECONDARY PHASE: CONCENTRATION OF BLOOD

Underhill and his co-workers [1] had the opportunity of studying twenty-one patients who were burned in a theater and found that, within a few hours, their blood became greatly concentrated. The hemoglobin content of the seriously burned patients was elevated to as high as 209 per cent. These authors concluded that when a hemoglobin content of 125 per cent is reached and sustained the maintenance of life becomes precarious and that a sustained hemoglobin content of 140 per cent is fatal.

The concentration, they pointed out, would so interfere with the functioning of the blood that it would produce failing circulation, inefficient carrying of oxygen with consequent oxygen starvation of the tissues, a fall of temperature and, finally, suspension of vital activities. They further showed that this stage may not reach its peak until thirty-six hours after the burn and may explain the early death of patients who survive the initial period of shock. Underhill, Kapsinow and Fisk [2] found that concomitantly with this change the nonprotein nitrogen level of the blood

From the University of California Surgical Service at the San Francisco Hospital, Division of the San Francisco Department of Public Health, and from the Department of Surgery, University of California Medical School.

1. Underhill, F. P.; Carrington, G. L.; Kapsinow, Robert, and Pact, G. T.: Blood Concentration Changes in Extensive Superficial Burns and Their Significance for Systemic Treatment, Arch. Int. Med. **32**: 31 (July) 1923.

2. Underhill, F. P.; Kapsinow, Robert, and Fisk, W. E.: Studies on the Mechanism of Water Exchange in the Animal Organism, Am. J. Physiology **95**: 302, 315, 325, 334 and 339 (Nov.) 1930.

was elevated and the level of blood chlorides was lowered; they concluded that the degree of concentration of the blood is an index of the patient's condition. In their opinion, this phenomenon explains the great part of the picture during the first twenty-four to thirty-six hours. These conclusions were also reached by Blalock [3] and Beard and Blalock [4] by experimental means. By the forcing of fluids during this period, the volume of the blood, as well as the cardiac function, is brought to normal. Recognition of this phase of the clinical picture, with suitable treatment, has helped greatly to lessen the early mortality in our cases of severe burns.

In spite of adequate treatment for shock and the concentration of the blood, and despite lack of evidence of infection under the eschar, occasionally a patient's condition may become critical during the first three or four days after a burn. In an attempt to explain deaths during this phase, Underhill showed experimentally that the intraperitoneal temperature may rise to 110 F. in animals with diffuse burns of the trunk. He felt that this penetration of heat to the abdominal cavity might play a significant part in the production of the pathologic appearance of the viscera usually attributed to toxemia from the burned area.

Because clinical, pathologic and experimental conditions occasionally simulate insufficiency of the adrenal cortex, Wilson, Rowley and Gray [5] suggested the use of adrenal cortex extract. They cited the cases of two critically ill children who they felt had been definitely benefited by this therapy.

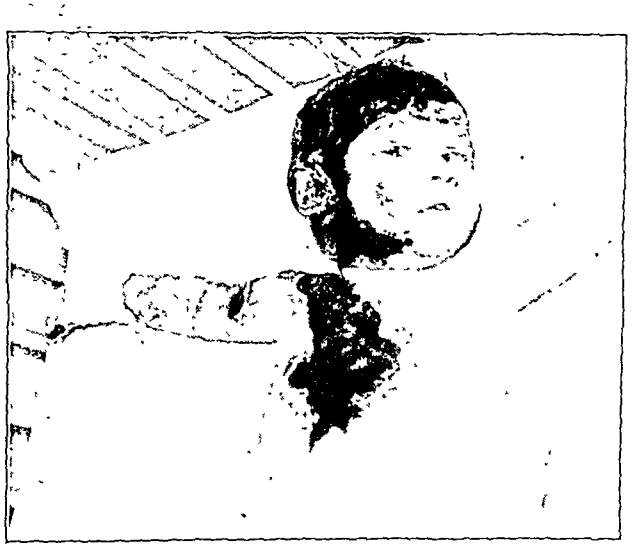

Fig. 1.—Third degree scald in a child 14 months of age, involving only 7 per cent of the surface of the body. He was treated by the tannic acid method. There was a moderately severe febrile reaction, with severe toxemia during the first week, although only a small area was involved. The child experienced convulsions, drowsiness and oliguria, but the urinary sediment was constantly normal.

It is evident that considerable doubt exists as to the cause of death in the small percentage of well treated patients with either slight or extensive burns who die in the first seventy-two to ninety-six hours.

5. Wilson, W. C.; Rowley, G. D., and Gray, N. A.: The Acute Toxemia of Burns, Lancet **1**: 1400 (June 20) 1936.

TERTIARY PHASE: TOXEMIA

There are two main hypotheses to be considered in attempting to explain the deaths which occur later. The older presupposed that there was some substance liberated from the burned area which made its way into the blood stream and produced the toxemia. Different authors have described a variety of split proteins as the causative agents of this toxic reaction.

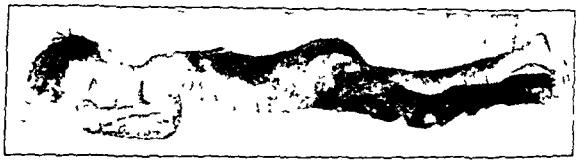

Fig. 2.—Third degree gasoline burn involving 45 per cent of the surface of the body in a boy 12 years of age. Shock, concentration of the blood and hypochloremia occurred. Septic toxemia from large infected granulating areas caused a marked elevation of temperature and pulse rate. Urinalysis showed nothing abnormal except the faintest possible trace of albumin. After the use of azochloramid dressings and daily baths the infection subsided. A steplike improvement followed each grafting of skin. Small deep grafts were used. Several transfusions were necessary.

Robertson and Boyd [6] burned the skin of rabbits. The burned skin was removed and grafted on unburned rabbits, and toxemia was said to have developed in the unburned rabbits, while control animals showed no change. The futility of attempting to graft burned skin from one animal to another is obvious to one familiar with dermal transplantations. Harrison and Blalock [7] repeated this work but were unable to produce signs of toxemia. Robertson and Boyd injected an extract of burned skin into guinea pigs and claimed to have produced a toxic syndrome which corresponded exactly to that seen in a burned patient. Kapsinow [8] repeated this work and found that the alcoholic content of the extract was sufficient to cause the symptoms in the animal, casting doubt on the theory that primary and secondary proteoses are present and produce toxemia, as advocated by Robertson and Boyd. He was unable to produce toxicity by injecting blood from burned patients into animals and performed other experiments to show that this idea was not tenable.

Averages of Annual Death Rates from Burns per Hundred Thousand (Conflagrations Excepted), with a Comparison of the Years 1911-1915 with the Years 1931-1935 (from the Metropolitan Life Insurance Company)

8. Kapsinow, Robert: Toxin of Extensive Superficial Burns, New Orleans M. & S. J. **85**: 195 (Sept.) 1932.

In 1924 Davidson,[9] working on the hypothesis that the toxemia of burns resulted from the absorption of broken down proteins from the site of the burn, introduced the use of tannic acid to coagulate the burned tissue and prevent toxic absorption. Working on the same hypothesis, Bettman[10] modified this method by applying silver nitrate, after an initial application of tannic acid, to shorten the period of the formation of the eschar and, by so doing, to prevent the absorption of the supposed split protein material.

In 1930 Underhill and his co-workers proved experimentally by injection of dyes and lethal doses of strychnine into the burned areas that no absorption from these areas occurred within the first twenty-four to thirty-six hours. They proved that instead fluids entered the burned tissue from the blood stream because of increased permeability of the capillaries. Reabsorption of this edema fluid then proceeded slowly for from five to six days. These authors felt that the early toxic symptoms resulted from dehydration, increased concentration of the blood and loss of blood chlorides and serum protein and concluded that an elevation of temperature after the first twenty-four to thirty-six hours is not the result of any absorption of decomposed protein from the burned areas but is caused by infection.

Aldrich[11] in 1933 proved to his satisfaction that the so-called toxemia which occurs from twelve to thirty-six hours after the burn is the result of infection. By extensive bacteriologic studies he found that after the first period of twelve hours material from 10 per cent of the severely burned areas yielded positive cultures with beta hemolytic or gamma streptococci as the predominating organism. This was also true of the large majority of minor burns. With obvious signs of sepsis, the concentration of these organisms increased until, after from forty-eight to fifty-six hours, pure cultures of streptococci could be obtained. In fatal cases, cultures of the blood showed streptococci and examination of the viscera showed evidence compatible with acute infection or sepsis. Aldrich introduced the use of a 1 per cent aqueous solution of gentian violet because of its bactericidal and bacteriostatic effect on gram-positive cocci as well as its escharotic value. He recognized the good results of the use of tannic acid but felt that they were due to the sealing off of the burn by a sterile eschar, with consequent prevention of infection, rather than to the lessening of absorption of broken down proteins. Recently Aldrich advocated the use of brilliant green with acriviolet (a mixture of acriflavine with gentian violet) because of its superior bactericidal and bacteriostatic properties.

Fig. 3.—The method of removing a large graft from a small child. This is impossible in many cases unless the Blair suction retractor is used.

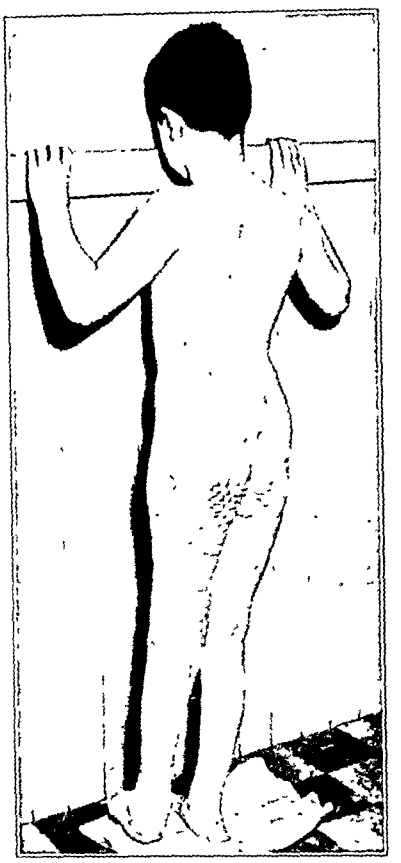

Fig. 4.—The patient shown in figure 2 eighteen months after the burn, showing healing by means of small deep grafts.

These clinical and experimental conclusions have been fortified by our observations and experiences and have stimulated changes in our therapy from time to time. At different periods we have stressed first one method and then another. The method to be described has been followed long enough to prove its value if it is carried out properly. In general it is planned to meet the successive phases of burns and their complications as they occur.

EARLY THERAPY

We always employ special nurses in the early period.

Shock.—No local therapy is instituted until this initial phase is corrected. The condition is combated by the usual means of heat, sedatives, fluids administered parenterally and transfusions of blood. A transfusion is always given to a patient with severe burns during the first few hours, even if he appears to be in excellent condition.

Tannic Acid Bath.—After the successful alleviation of shock, local therapy is started. For some time we used the tannic acid spray method. It was given up because many hours were required for the formation of the eschar, the patient was kept moist for too long a time and the method was difficult to use for burns which covered the dorsal as well as the ventral surfaces of the body.

Tannic acid jellies, although excellent for emergency dressings, usually require two or three applications for the formation of an eschar, over a period of from twenty-four to seventy-two hours. Frequently, with the change of dressings, portions of the eschar are pulled away, allowing infection to enter.

11. Aldrich, R. H.: The Role of Infection in Burns, New England M. J. 208:299 (Feb. 9) 1933.

We now favor the use of the tannic acid bath as described by Wells.[12] It helps to combat shock, facilitates débridement and starts formation of the eschar. Enough tannic acid powder is placed in a warm bath (from 90 to 100 F.) to give a muddy color. After an initial burning sensation of short duration, the patient usually relaxes completely in the tub. All blebs, previously applied unguents and loose necrotic tissue are removed gently by means of sterile forceps and scissors. The surrounding skin is cleansed with gauze soaked in green soap and water. During the débridement and cleansing of the burned area, which usually last from sixty to ninety minutes, the bath is changed two or three times as necessary to dispose of the débris.

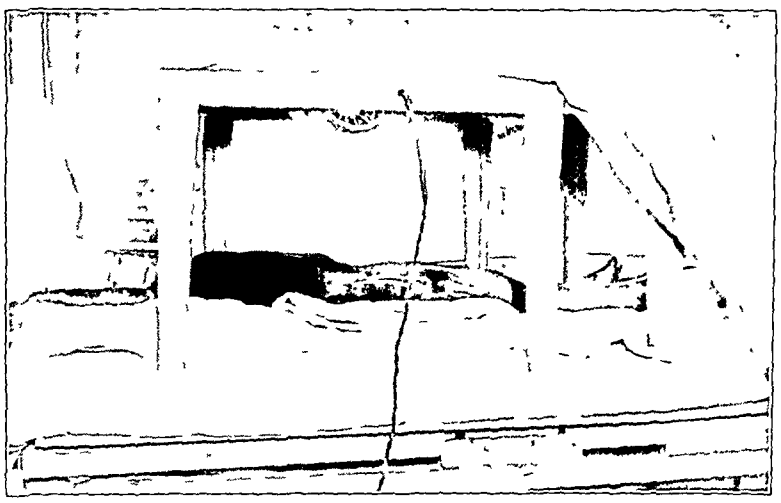

Fig. 5.—H. S., a girl 7 years of age, with 20 per cent of the body involved by second and third degree burns, immediately after tanning. Shock, concentration of blood and hypochloremia occurred. She was treated by the tannic acid bath, silver nitrate and gentian violet method.

Although treatment by the production of an eschar was introduced in 1925, we still see many severely burned patients treated by means of unguents. We emphatically condemn their use in cases of severe burns. This is the one type of initial treatment which may interfere with modern therapy. If there is any suspicion that the burn may be extensive or deep and no escharotic preparations are available, it is far wiser to wrap the patient in clean linen and rush him to an institution where proper therapy can be carried out than to treat him with unguents.

Mentioned only to be condemned is vigorous débridement of burns or excision of the burned area with the patient under anesthesia. These methods, in our hands, have tended to induce or aggravate shock. We place exsanguination followed by transfusions in the same category. These procedures are too radical.

Silver Nitrate.—After satisfactory débridement, the patient is dried with sterile towels. Gauze soaked in 10 per cent solution of silver nitrate is then applied by blotting it on the burned area. An immediate tan is produced. This saves from twelve to seventy-two hours, required for the production of a tan by other methods, and seals the burned area long before infection can take hold. The element of time is extremely important, as the treatment of a burn should conform to the general surgical principle that an open wound must be closed within six or eight hours if it is to be considered free from contamination. No cases of poisoning from the absorption of silver have been encountered, the reason probably being that little absorption occurs from the burned areas at this time.

The patient is then placed on a sterile sheet, pressure being kept off the burned areas. Particular emphasis is laid on the fact that the burn should be treated as a sterile surgical wound. If every precaution is not taken, the eschar will soon show varying degrees of infection. A large cradle is placed over the child to keep the bed clothes away from the burn (fig. 5). The temperature of the tent is usually kept around 85 or 90 F. in order to keep the patient comfortably warm and the eschar from becoming moist.

Gentian Violet.—The entire burned area, including its edges, is treated with a 1 per cent aqueous solution of gentian violet applied with sterile gauze pledgets several times a day for the first few days. In this manner the surface of the burn and the surrounding skin are kept free from organisms. It is important to give this treatment three or four times a day in order to keep dry small fissures or other areas which might otherwise become moist as a result of pressure, motion or perspiration (fig. 2).

With deep burns completely encircling the hands or fingers, the tannic acid and silver nitrate method is not used, because of the danger to the circulation by its constricting action. In this location, gentian violet alone or saline compresses should be substituted.

Prevention of Dehydration and Concentration of the Blood.—During the early phase, most patients will take fluids by mouth, but, if they are unable to do so, fluids should be administered parenterally to combat dehydration, concentration of the blood and loss of chlorides. Fluids such as fruit juices, broth and milk should be forced. For children with large burned areas, it is our policy to give transfusions during the first twenty-four hours as prophylaxis against the recurrence of shock.

Fig. 6.—H. S., three weeks after the burn, showing the remaining eschar, which is still dry and free from infection.

We do not advocate the use of continuous intravenous therapy, because of the danger of thrombophlebitis, bacteremia and septic emboli. The intake of fluids and the urinary output should be recorded carefully. If edema ensues, the quantity of fluids should be lessened. In our experience, oliguria has been the first sign of renal injury, usually occurring after a few days; in only a few cases have we been able to demonstrate casts and red blood cells in the urine except as a terminal finding.

12. Wells, D. B.: The Aseptic Tannic Acid Treatment of Diffuse Superficial Burns, J. A. M. A. **101**: 1136 (Oct. 7) 1933.

LATE THERAPY

As a rule, within seven to fourteen days the edge of the eschar starts to loosen and curl up. If the burn is no deeper than second degree, epithelium creeps in from the sides and from residual islands beneath the eschar, covering the burned area. As the eschar loosens, it is trimmed away and gentian violet is applied. If purulent material collects under a portion of the eschar, the eschar is removed locally and that part of the burn is painted with gentian violet several times a day. Following this routine carefully, we have seen no spread of the infection under the eschar.

Fig. 7.—H. S.; the clean granulating surface is ready for skin grafting six and a half weeks after the burn

After three weeks we assume that the remaining eschar covers third or deep second degree burns and that spontaneous epithelization will not occur. This densely adherent eschar therefore is removed to allow the formation of granulation tissue. At first we applied compresses to all eschars, feeling that this was the simplest manner of removing them. Many patients, however, still had adherent eschar even after two weeks of this treatment, so, although we still remove small areas by means of compresses, for large areas we favor excision of the eschar with the patient under light anesthesia. If necessary we combat operative shock by preoperative transfusion. After the eschar is removed, the burned area is treated as a wound and the formation of granulation tissue is encouraged in preparation for the grafting of skin.

Present day advertising may mislead the inexperienced to feel that the qualities of certain products are sufficient to heal a burn during this stage. Although this may be true of minor burns, it is never true of severe burns; these always result in wounds denuded of epithelium and must be treated as such.

It is extremely important to anticipate and combat late complications such as anemia, septic toxemia and contractures. If large granulating areas are present for a long time, the patient soon presents a picture of exhaustion despite an abundant diet and transfusions. The best means of preventing such difficulties is to graft skin over all granulating areas as soon as feasible.

Preparation for grafting is carried out by means of daily tub baths, the application of saline compresses and saline jelly and the use of diluted solution of sodium hypochlorite or azochloramid. We have found the last to be of considerable value in treating large infected granulating areas. Only one dressing is required daily, and the patient usually shows an increase in appetite, requires fewer sedatives and shows an improvement in morale as compared with those who have several painful changes of dressings each day. We feel that the lives of many of our most severely burned patients have been saved by this method.

Whenever possible we recommend the covering of granulating areas by grafts of intermediate thickness, after the method of Blair and Brown [13] (fig. 3). With very large areas it may be impossible to use this type of graft because of insufficient donor skin. In such cases we use the small deep grafts of Davis [14] (fig. 4).

Patients who are recovering from severe burns do not tolerate a great deal of surgical work. For those showing exhaustion one must plan short procedures with light anesthesia, often preceded by transfusions.

In the correction of healed contractures —which frequently cannot be prevented— every attempt is made to use grafts of intermediate thickness for repair.[15] Although this type of graft has limitations, it is amazing how frequently and efficaciously it may be used, and by this method many involved extensive procedures may be avoided. We have found that only a small proportion of our patients require the use of grafts of the full thickness of the skin or pedicles of skin and subcutaneous tissue.

REPORT OF CASE

H. S., a girl aged 7 years, was admitted to the University of California Hospital Feb. 2, 1937, with severe burns over the right side of the thorax, axilla and abdomen. Immediately after the accident (8:15 p. m.) she was rushed to an emergency hospital, where a tannic acid and merthiolate jelly (amertan) was applied and a sedative given. She entered the University of California Hospital an hour later, in shock, and was wrapped in a sterile sheet and hot blankets. Having sufficiently recovered from shock by 10:30 p. m. (two and a half hours after the burn) she was placed in a tannic acid bath for about ninety minutes. During this time she was completely relaxed and free from pain. The bath was changed three times before débridement was complete.

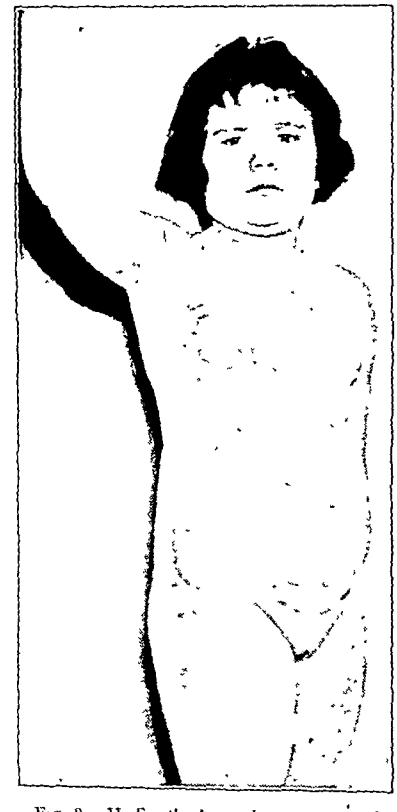

Fig. 8.—H. S.; the burned area is entirely healed two weeks after the application of split grafts and two months after the burn.

She was dried with sterile towels and painted with a 10 per cent solution of silver nitrate followed by a 1 per cent aqueous

solution of gentian violet. Within half an hour her eschar was complete and she was placed on a sterile sheet, naked under a cradle from which was suspended an electric light bulb (fig. 5). It was computed that she had suffered second and third degree burns of 20 per cent of the total surface of the body.

During this period fluids were forced by mouth and a clysis of 500 cc. of Ringer's solution was given, as well as a transfusion of 350 cc. of whole blood. The hemoglobin content was 110 mg. and the plasma chloride content 495 mg. per hundred cubic centimeters of blood. The red blood cell count was 6,000,000. Two days later the plasma chloride content was 574 mg. Urinalysis gave consistently negative results throughout her stay in the hospital.

For the first few days her temperature and pulse rate remained somewhat elevated. Within seven days after the burn there had developed a mild secondary anemia which improved after a transfusion of blood. The eschar began to lift at the edges by the seventh day. The elevated portions were trimmed away and the adherent edges were painted with gentian violet. On the twenty-fourth day the remaining eschar (about 35 per cent) was removed with the patient under light anesthesia (fig. 6).

After the removal of the eschar, she was placed in a tub bath for two or three hours each day for nineteen days before her granulations were considered clean enough to permit the grafting of skin. After each tub bath the granulating areas were dressed with strips of fine mesh gauze, 4 by 8 inches in size, saturated with a mixture of one part of azochloramid in glyceryl triacetate (triacetin) to three parts of Peruvian balsam. We have found that one dressing of this mixture daily is adequate to prevent infection. For two days before grafting, compresses of physiologic solution of sodium chloride were applied to the area.

On the nineteenth day after the removal of the eschar, four large split grafts were removed from the left thigh by the Blair method and sewn into the defect on the thorax (fig. 7). A spica bandage of dressings, gauze roll bandages and wide adhesive tape was sufficient for immobilization. Rubber tubes were included in the dressings to allow the introduction of warm saline solution. The dressings were changed for the first time on the third day; then daily dressings were done, pressure being reapplied for seven days. The patient was discharged from the hospital March 28, eleven days after the grafting was done and fifty-five days after the burn (fig. 8). One month after discharge, the motions of the shoulder girdle were normal.

SUMMARY

1. The prognosis of severe burns in children is so uncertain that all children with such burns should be hospitalized promptly.

2. The mortality of burns has been lessened greatly because of the improved therapy now in use.

3. The use of unguents in the treatment of severe burns has been condemned.

4. The tannic acid bath, silver nitrate and gentian violet method is the treatment of choice for the early local treatment of burns.

5. A review of the literature reveals experimental and clinical evidence to suggest that infection rather than absorption of toxic products is the cause of late toxemia in cases of burns.

6. Few constitutional changes occur if infection is prevented by the early formation of a sterile eschar.

7. The early grafting of skin over granulating areas is urged for the prevention of septic toxemia and contractures.

8. The use of grafts of intermediate thickness (Blair) is recommended whenever possible.

340 Post Street.

FRACTURES OF THE SPINE COMPLICATING METRAZOL THERAPY

BASIL T. BENNETT JR., M.D.
AND
CHARLES P. FITZPATRICK, M.D.
PROVIDENCE, R. I.

Convulsive therapy was first advanced by Ladislaus von Meduna of Budapest, Hungary. He conceived this form of therapy on the basis of reports as to the infrequency of the occurrence of both epilepsy and schizophrenia in the same individual and the fact that patients known to have schizophrenia had greatly improved or had recovered when spontaneous epileptic seizures developed. Meduna [1] said "The theoretical basis for the therapy with cardiazol lies in the assumption that a certain biochemical antagonism exists between the convulsive state and the schizophrenic process."

Meduna first experimented with animals, producing convulsions by injecting camphor. Jan. 2, 1934, he gave his first injection of a 25 per cent solution of oleum camphoratum to a patient for the purpose of producing a convulsion. He [2] found one patient in whom he could not produce a convulsion with camphor, so metrazol (cardiazol) was substituted. Cardiazol, or metrazol, is an analeptic, and these are the European and American trade names, respectively, for pentamethylentetrazol, which was synthesized by Prof. K. F. Schmidt [3] of Heidelberg, during experiments directed at the synthesis of water-soluble substances having the therapeutic properties of camphor. Meduna's [2] report on the result of cardiazol therapy with twenty-six schizophrenic patients was submitted for publication in January 1935.

The treatment was first introduced to this country by Dr. Emerick Friedman [4] of Buffalo City Hospital, who reported a series of twenty cases at the meeting of the American Psychiatric Association in May 1937. In November 1937 Kennedy [5] gave a report of 1,000 cases that had been treated throughout Europe. Several hundred cases of metrazol treatment have been reported in this country, and we have had verbal reports of at least 200 cases that have not appeared in the literature. With the rapidly increasing popularity of this form of therapy, it would seem reasonable to assume that as many as 4,000 patients have received some form of convulsive therapy.

Since Nov. 18, 1938, seventeen patients (three males, fourteen females) have received metrazol therapy at Butler Hospital. The number of convulsions produced in each case has varied from two to fifteen, with a total of 117 convulsions for the entire group. Eight of the patients treated have complained at some time of pain in the back. Such complaints have occurred most frequently after the first or second convulsion, although one patient did not complain of pain until three weeks

From Butler Hospital.

after treatment was discontinued. This symptom has varied from slight discomfort to severe pain. Several of the patients have exhibited localized tenderness to light percussion over the involved portions of the spine. Only one patient complained of severe pain, and this was of short duration. This patient also presented evidence of having difficulty in body movements and, the first for whom roentgenograms were made, presented symptoms more severe than those observed in any other patient. The roentgenograms showed compressed fracture of the eleventh and twelfth dorsal vertebrae. This was considered a rare and unfortunate occurrence, the first of its nature reported in the history of metrazol therapy. However, subsequent x-ray examinations revealed compressed fractures of the dorsal spine in all patients who had complained of backache.

Fig. 1 (case 1).—Obvious compression fracture of the body of the twelfth dorsal vertebra, upper portion, with zone of increased density; slightly compression of the anterior inferior portion of the body of the eleventh vertebra, and slight kyphosis.

A brief report on the patients complaining of pain in the back, with a report of the x-ray examinations, will best convey the problem that is being called to the attention of those employing convulsive therapy.

REPORT OF CASES

CASE 1.—A. L., a man aged 48, who had three convulsions, the first Nov. 30 and the last Dec. 7, 1938, complained after the first convulsion of slight pain in his back, which increased after the second treatment. Immediately after the third convulsion, while still very confused, he gave evidence of experiencing severe pain. This lasted for approximately thirty minutes, with occasional attacks in decreasing frequency for three hours. At this time the pains were localized high over each lumbar region several inches from the midline. The patient refused to stay in bed after the first six hours and presented symptoms simulating lumbago. There was a subsidence of symptoms from day to day. When closely questioned, the patient spoke of transient pain in the anterior abdominal wall. It was for this reason that an x-ray examination was made December 15.

Physical and neurologic examinations revealed a questionable rigidity of the muscles of the back and patchy areas of mild hyperesthesia over the twelfth dorsal root distribution bilaterally, most noticeable on the right.

On x-ray examination December 15 the body of the eleventh dorsal vertebra showed a partial compression fracture of the anterior portion inferiorly. There was definite buckling near the anterior-inferior angle, with localized condensation of the bone. The body of the twelfth dorsal vertebra showed a more extensive compression fracture, with definite concavity of the upper surface and a uniform diffuse zone of condensation extending across the entire upper surface. The anterior margin of the body of the twelfth vertebra was distinctly lower than the posterior margin. Likewise the vertical margin on the left was narrower than the corresponding right margin. There was slight lateral scoliosis at the junction of the eleventh and twelfth bodies in the anteroposterior views. In the lateral views, there was slight but distinct kyphosis at the same level, with definite narrowing of the anterior and particularly the posterior portion of the intervertebral space. No other evidence of fracture or dislocation could be seen in the vertebrae examined. The posterior portions of the lower five ribs appeared to be intact.

CASE 2.—J. O., a woman aged 30, who had her first convulsion Nov. 23, 1938, and her fifteenth and final one Jan. 16, 1939, occasionally mentioned interscapular pain in the back after the first or second treatment. During the second and third weeks in January her complaints became more pronounced, for the most part being expressed just before treatments, when she was somewhat apprehensive. January 20 the patient mentioned pain in the anterior part of the chest, for which reason treatment was omitted that day. In response to later questioning on the same day, all symptoms were minimized, the patient being unable to state definitely in which chest wall the pain was experienced. She thought x-ray examination unnecessary.

Physical examination gave negative results. Neurologic examination revealed patchy areas of slight hyperesthesia over the sixth and seventh dorsal root distribution.

On x-ray examination January 20 the fourth and fifth dorsal vertebrae showed slight compression fractures of their bodies, with definite irregular condensation just below the superior surface of each body. The body of the sixth dorsal vertebra had a compression fracture of somewhat greater degree. There was a definite wedge formation of this body, with a narrow anterior vertical margin. This body also presented a zone of increased density just below its superior surface. The body of the seventh dorsal vertebra showed a slight compression fracture along its upper part, with irregularity of the superior surface and a zone of increased density below it. This vertebra showed a slightly lower lateral margin on the left side as compared with the right. The fifth body, on the other hand, showed a narrower right margin as compared with the left. There was slight kyphosis in this region centering at the level of the wedge-shaped sixth body. There was also moderate S-shaped lateral scoliosis in this region, with slight rotation. The intervertebral spaces did not seem to be appreciably changed in size, although there was slight narrowing anteriorly.

The remaining upper and lower dorsal vertebrae did not show any evidence of fracture, dislocation or other bony injury. The bony portions of the ribs also appeared to be intact.

Fig. 2 (case 2).—Compression fractures of the bodies of the fourth, fifth, sixth and seventh dorsal vertebrae, all showing concavity with zones of increased condensation in the upper portions. The body of the sixth vertebra shows distinct wedge shape.

CASE 3.—E. O., a woman aged 41, who had two convulsions, Jan. 13 and Jan. 20, 1939, complained of slight interscapular pain for three or four hours after the first treatment.

After the last seizure she complained of the same pain and has continued to experience some discomfort.

Physical and neurologic examinations gave negative results except to reveal some tenderness to slight percussion over the upper part of the dorsal spine.

On x-ray examination January 23 the bodies of the fifth and sixth dorsal vertebrae showed slight compression fractures of their superior portions. There was irregularity along the superior surfaces of both bodies, with a slight localized increase of calcium deposition. The process was slightly more marked in the fifth body. The anterior portions of the interspaces

between the fourth, fifth and sixth vertebrae showed slight narrowing. No other fracture or dislocation could be detected in the dorsal vertebrae. The ribs also appeared to be intact.

CASE 4.—L. G., a woman aged 31, who had a total of eleven convulsions from Nov. 18 to Dec. 23, 1938, began early in the course of treatment to complain of interscapular pain in her back. After treatment was discontinued she mentioned that about the only time she noticed pain was when playing the piano for long periods. This patient was discharged from the hospital Jan. 17, 1939.

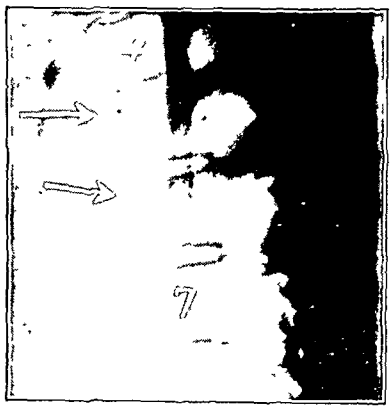

FIG. 3 (case 3).—Slight compression fracture of the superior portion of the body of the fifth dorsal vertebra and probable compression fracture of the upper portion of the body of the sixth vertebra.

Because of the fractures discovered in other cases of pain in the back, she was called into the hospital. The history while she was out of the hospital was that on turning her trunk she occasionally experienced discomfort.

Physical and neurologic examinations gave negative results.

On x-ray examination January 24 the bodies of the fifth and seventh dorsal vertebrae showed definite compression fractures. Both these bodies showed wedge formation, which was slightly more apparent in the seventh. There was a distinct increase in calcium deposition just below the superior margin of the seventh body, indicating slight reparative reaction. Slight narrowing was seen in the anterior portions of the intervertebral spaces from the fourth to the seventh vertebrae. Slight kyphosis was noted on the lateral view. The remaining dorsal vertebrae and the ribs showed no evidence of fracture, dislocation or other bony injury.

CASE 5.—L. S., a woman aged 48, who had five convulsions between Dec. 9 and Dec. 30, 1938, during this time complained of backache. She was discharged Jan. 3, 1939. A member of the hospital personnel visited her home January 12 and reported that she was complaining of pain in her back. On account of this she was called into the hospital January 24.

Physical and neurologic examinations gave negative results.

On x-ray examination January 24 the body of the fifth dorsal vertebra presented a definite but slight compression fracture involving the superior portion chiefly. There was a definite decrease in the vertical height of the body, with a slight bulging at the anterior superior margin. There was a zone of increased calcium deposition just below the superior surface. This indicated a slight reparative reaction. The superior surface of the body of the sixth dorsal vertebra showed slight irregularity and increased thickening, suggesting a probable slight compression fracture. The interspaces between the fourth, fifth and sixth vertebrae showed slight narrowing anteriorly. There was no definite kyphosis. The remaining dorsal vertebrae showed no evidence of definite bony injury or disease. The ribs all appeared to be intact.

CASE 6.—A. H., a woman aged 52, who had three convulsions Jan. 13, 16 and 20, 1939, for the first time on January 24 mentioned having pain in her back, which she attributed to a mild infection of the respiratory tract. In response to questioning January 26, she showed little concern but admitted having noticed a disturbance after each treatment and described it as discomfort with no definite pain. The greatest discomfort was observed when she was sitting to have her hair dressed.

Physical and neurologic examinations gave negative results.

On x-ray examination January 27 the body of the seventh dorsal vertebra showed a distinct compression fracture of its upper portion, with definite but slight wedge formation. The anterior surface of this body was slightly lower than the posterior surface. The superior surface was irregular and just below it was a zone of slightly increased density. In one of the lateral views the superior surface of the body of the sixth dorsal vertebra seemed slightly irregular and suggested the possibility of slight compression. The evidence, however, was not definite. The remaining dorsal vertebrae and the ribs showed no evidence of definite fracture or other bony injury.

CASE 7.—D. D., a woman aged 35, who had eleven convulsions from Nov. 23, 1938, to Jan. 30, 1939, spoke on a few occasions of her back hurting during the first part of the treatment. Both January 24 and 26 she denied having any pain in the back except slight discomfort in the early morning.

Physical and neurologic examinations gave negative results.

On x-ray examination January 27 the bodies of the fifth and sixth dorsal vertebrae showed compression fractures involving their upper portions. There was definite concavity of the superior surfaces of both of these bodies, with a definite zone of condensation adjacent. The concavity was more pronounced in the body of the sixth vertebra, which also showed slight wedging. The anterior surface of this body was definitely lower in height than the posterior surface. Slight kyphosis was visible in the lateral view, centering at the level of the body of the sixth vertebra. The remaining dorsal vertebrae did not show any positive evidence of bony injury. The ribs likewise appeared to be intact.

CASE 8.—L. G., a woman aged 48, who had eight convulsions from Nov. 18 to Dec. 23, 1938, made no complaint whatever and was discharged from the hospital Jan. 3, 1939. Her husband, while on a business visit to the hospital January 28, casually mentioned that his wife had some pain in her back and sides which was attributed to unaccustomed housework and digestive disturbance.

Physical examination disclosed slight tenderness over the lower half of the dorsal spine. It has as yet been impossible to have the patient in for neurologic examination.

On x-ray examination January 28 the tenth dorsal vertebra showed a very marked compression fracture of its body, with considerable wedge formation, the anterior surface being approximately two thirds the height of the posterior surface. There was considerable condensation in the upper half of the body, especially close to the compressed superior surface. There was likewise definite anterior bulging in the neighborhood of the anterior superior angle. The left margin of the body was distinctly lower in height than the right margin. The interspace between the ninth and tenth vertebrae appeared to be slightly narrowed, especially anteriorly. The seventh dorsal vertebra showed a partial compression fracture involving its superior surface, with concavity and slight condensation just below the surface. The remaining dorsal vertebrae did not show any evidence of fracture, dislocation or other bony injury. In the lateral views there did not appear to be any obvious kyphosis at the level of the injured tenth vertebra.

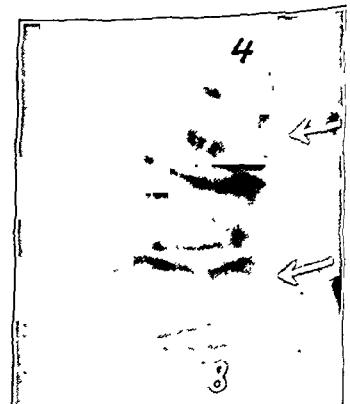

FIG. 4 (case 4).—Compression fractures of the bodies of the fifth and seventh dorsal vertebrae. Both show slight wedge formation but especially the seventh. There is slight kyphosis.

With the cases as reported, it is seen that in 100 per cent of all cases in which there was a complaint of pain in the back there was definite pathologic change of traumatic origin in one or more dorsal vertebrae. Of the seventeen patients treated, these represented all who complained of pain in the back (47 per cent); none of the other patients had x-ray studies. There had

been no variation of the usual procedures in this series which would account for any greater occurrence of such complications. However, I have not heard of any one previously reporting observations of this nature.

Walk and Mayer-Gross [6] reported: "The more severe injuries which we have found recorded, and all of which occurred with cardiazol (metrazol), are fractures of the neck of femur, including one bilateral case (Kerstens); various fractures of the humerus, again including one bilateral case (Kraus); fractures of the scapula (Briner); dislocations of the shoulder and of the jaw." In addition we have heard of cases of fractures of the transverse processes of the spinal vertebrae.

The literature occasionally mentions the presence of pain in the back but gives no special attention to it; e. g. Briner,[7] "Sometimes muscle cramps appear, predominantly in the back"; Walk and Mayer-Gross,[6] "In others the complaint was of pains in the limbs, back or head, persisting after recovery from the fit," and Kennedy,[5] "Patients who can cooperate say that they are tired and sometimes complain of backache." We have heard verbal statements to the effect that a large percentage of all patients have complained of pain in the back.

The end result and associated complications of the condition here reported are yet to be seen. As a late complication, even with some of the patients who might not have sustained a fracture, symptoms resulting from a herniated or ruptured intervertebral disk will have to be considered. Mixter and Ayer [8] in reporting what was considered a typical case history of herniation of a disk into the lumbosacral canal said: "The present symptoms are similar to pain experienced six years ago which came on suddenly when lifing a heavy bale of cloth, necessitating bed rest for five weeks. In the intervening four years he has been well and active." Walsh and Love [9] noted an intermittence of symptoms in 86 per cent of cases of protrusions of the lumbar disk, the average duration of symptoms before operation being six years.

In view of the relatively short period during which convulsive therapy has been employed, the average delay in the occurrence of distressing symptoms due to herniation of an intervertebral disk and the demonstrable pathologic change in the cases here reported, the possibility of damage to the intervertebral disk cannot be discarded. It would be interesting as well as beneficial to make iodized oil and spinal fluid protein studies to determine the absence or presence of any disk herniation. Also, an x-ray examination of metrazol-treated patients not complaining of pain in the back would be of interest in comparison with these that have shown definite changes in the vertebral bodies.

This preliminary report directs attention to a previously undescribed condition, compression fracture of the vertebrae resulting from metrazol convulsive therapy. The problem of combating this detrimental feature of an otherwise beneficial therapy in the treatment of mental illness is being studied with orthopedic and roentgenologic consultants, and the results obtained will be presented in a later contribution.

COMMENT

By Dr. Isaac Gerber (consultant roentgenologist to Butler Hospital): Compression fractures in the upper half of the dorsal spine are relatively uncommon. In this group of eight cases, a complete series of stages in the production of compression fracture has been obtained. The fractures vary from the very obviously advanced compression seen in cases 1 and 8 to the very minimal changes observed in case 6. Some of the changes were so slight as to warrant a label of questionable (body of the sixth dorsal vertebra in case 5). In all cases, however, at least one vertebral body showed characteristic injuries sufficient to warrant a positive diagnosis of compression fracture of some degree.

At first it was thought that the extent of injury to the dorsal vertebrae was proportional to the number of convulsions produced. Patient 2, for example, who had fifteen convulsions, had the widest extent of damage, covering four vertebrae. Likewise patient 3, with two convulsions, showed only slight changes in two adjacent vertebrae, which could easily have been overlooked. More careful analysis, however, showed that one of the most advanced lesions occurred with only three convulsions (case 1). It seems probable therefore that the severity of the individual convulsions may be as important as the number.

Fig. 5 (case 8).—The body of the tenth dorsal vertebra shows a marked compression fracture with considerable wedge formation. The body of the seventh vertebra shows partial compression of the superior surface with definite concavity and slight condensation just below the surface.

The mechanism of the force producing these fractures consists of repeated violent flexions of the body with both the clonic and the tonic convulsions. The concavities noted on the upper surfaces of many of the damaged bodies are probably due to pressure from the nucleus pulposus in the intervertebral disk.

The production of repeated trauma to the vertebral bodies by a series of closely spaced convulsions constitutes a state very much resembling the supposed etiologic factor in the production of Kümmell's disease. This disease is a peculiar osteitis of the vertebral body with wedge-shaped deformity, which at present is believed to result from repeated strains or slight trauma. Further consideration will have to be given to this aspect in the closer analysis and study of these cases, which will be made later.

By Dr. Henry F. McCusker (visiting orthopedist at Rhode Island Hospital): In this series, the majority of the fractures occurred in an uncommon location, the level of the fifth, sixth and seventh dorsal vertebrae. Compression fractures of the bodies of the dorsal verte-

brae usually occur in the upper five or in the lower three vertebrae. The usual precipitating trauma is a fall with the spine thrown into sharp anterior flexion, the jackknife position. In those convulsions which I have observed, the forward flexion occurring during the clonic phase appeared neither violent nor of sufficient range to be termed jackknifing. Whether these fractures were caused by trauma during a single convulsion or were the end result of repeated trauma suffered during successive convulsions cannot be answered with any degree of certainty, but symptoms referable to the back occurred early in the course of treatment in several of the cases. Incidentally, it should now be apparent that careful x-ray examination should be made in every case no matter how slight the backache. The slight symptom alone may deceive the physician as to the presence of this serious lesion.

Because of the high incidence of these fractures occurring during treatment, some method must be devised to control the motions of the spine during the convulsive state. A modification of the curved Bradford frame to which the patient can be strapped is now under consideration, but the details have not yet been worked out completely. Until the patient can be protected by adequate apparatus this form of treatment must necessarily be suspended.

The majority of the cases here reported show but slight disability from the spinal lesion. At this time it is impossible to prophesy what late results may ensue, such as the formation of definite kyphosis due to further collapse of the involved vertebral bodies (Kümmell's disease) or further narrowing of the intervertebral spaces with consequent symptoms due to disturbance of the intervertebral disks. X-ray reexamination every three months at least will be required until complete healing of the fractures has occurred.

SUMMARY

1. Seventeen patients were treated, eight of whom complained of backache.

2. All patients complaining of pain in the back, regardless of its mildness, showed x-ray evidence of compressed fractures and constituted 47 per cent of the patients treated.

3. Pain usually appears early in the course of the treatment, though in one of the eight cases it did not develop until three weeks after the treatment had been discontinued.

4. Slight tenderness on percussion of spinous processes was present in some of the cases.

5. Patients 1, 2 and 8 presented symptoms suggestive of root pain, patients 1 and 2 having ill defined areas of hyperesthesia. Circumstances have prevented examination of patient 8.

6. Disabling effects are practically nonexistent only patient 1 showing evidence of disability, and this being slight.

7. It is questionable whether the fractures are the result of a single severe convulsion or repeated convulsions.

8. The question of late complications resulting from herniation or rupture of the intervertebral disk cannot as yet be answered.

9. All fractures here seen were confined to the dorsal vertebrae.

TRAUMATIC COMPLICATIONS OF CONVULSIVE SHOCK THERAPY

A METHOD OF PREVENTING FRACTURES OF THE SPINE AND LOWER EXTREMITIES

W. R. HAMSA, M.D.
AND
A. E. BENNETT, M.D.
OMAHA

Convulsive shock therapy has been employed for several years in the treatment of severe psychoses without sufficient attention being paid to undesirable complications.[1] We are reporting seven cases of spontaneous fractures which have occurred during the convulsions induced by metrazol (pentamethylenetetrazol). We shall also suggest a procedure for preventing most of these catastrophes.

Lehndorff [1a] was the first to report fractures resulting from the severe muscular contractions associated with tetanus. Later Sonntag [2] reported fractures of the elbow and dislocations of the shoulder, Baisch [3] discussed fractures of the femoral neck and Wilhelm [4] described fractures of the forearm. All these fractures occurred during tonic convulsive seizures of tetanus. Roberg [5] made a comprehensive study of the spinal changes and concluded that the forces exerted by tetanic muscular contractions produced compression fractures of the midthoracic vertebral bodies, usually those of the fifth and sixth vertebrae, in definite contrast to ordinary traumatic compression fractures, which center about the body of the first lumbar vertebra.

Fig. 1 (case 1).—Impacted fracture of the right femoral neck.

The muscular contractions associated with tetanus are comparable to those induced by convulsive shock therapy as used in the treatment of psychoses. Meduna and Friedman [6] recently collected 3,000 cases of shock therapy and found that in 1.1 per cent there was evidence of "mechanical complications." No mention,

however, was made of the nature or severity of these complications. From our own experiences, we are convinced that in this form of therapy injuries to the skeletal system occur much more frequently than is generally appreciated. The fact that psychotic patients are often uncooperative may contribute to the recognition of only major accidents. Since we have encountered three fractures in a series of some 800 shock treatments, a restudy is being made of some of the

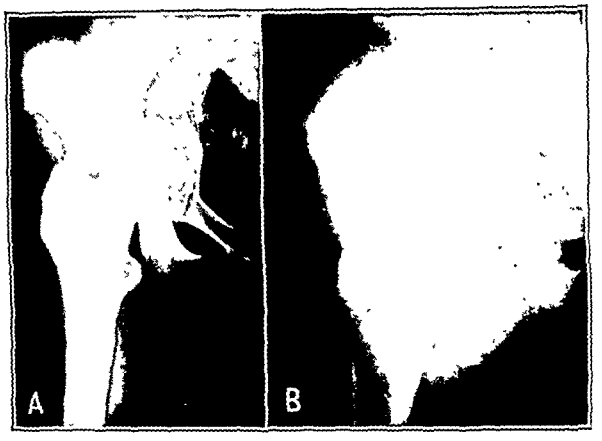

Fig. 2 (case 2).—*A*, fracture of the right acetabulum with intrapelvic dislocation of the femoral head. *B*, appearance after reduction, showing an additional chip fracture of the femoral head.

earlier cases, and old fractures and injuries are being found. We believe that the frequent complaints of backache after treatment formerly thought to be muscular in origin very likely are from vertebral trauma, e. g. in cases 3 and 4. A high incidence of fractures will naturally deter the use of this very valuable procedure. Metrazol has proved most useful in the treatment of severe depressive psychoses.[7] The problem is so important that preventive measures must be devised if the treatment is to survive.

The following cases are representative of the mechanical accidents that can occur during a metrazol shock. All treatments were given by neuropsychiatrists who are thoroughly familiar with this form of therapy and in institutions well equipped for such procedures.

CASE 1.—A man aged 22, given a course of insulin shock therapy for catatonic schizophrenia in September and October 1937 and, because of a mild relapse, one metrazol shock October 26, was subsequently discharged in spite of a vague ache in the right hip. On return examination, November 3, he was still not using or bearing weight on the right leg. Physical examination revealed the right leg in 15 degrees external rotation and 20 degrees flexion contracture, the right leg three-fourths inch shorter than the left, the trochanter above Nelaton's line and axial compression of the femur painless. Roentgenograms of the pelvis disclosed an impacted fracture of the right femoral neck in 20 degrees varus, the lateral view showing good alinement (fig. 1).

CASE 2.—A woman aged 21, with hebephrenic schizophrenia, was given a fourth metrazol shock Feb. 12, 1939, and during the convulsion a crumbling sound was heard, referred from the pelvis. Physical examination disclosed a narrowed right hip area, with depressed trochanter and three-fourths inch shortening of the right leg. Roentgenograms revealed a fracture of the right acetabulum with intrapelvic dislocation of the femoral head (fig. 2 *A*). With the patient under avertin anesthesia, the fracture and dislocation were reduced by manipulation and strong fracture table traction as described by Orr.[8] Roentgenographic recheck gave satisfactory results, showing an additional chip fracture of the femoral head (fig. 2 *B*). A steel pin was inserted through the proximal crest of each tibia and immobilization carried out with a double hip spica cast. Thirty pound traction to a cross bar was instituted. Subsequent studies of the blood showed calcium 10.9 mg. and phosphorus 3.5 mg.

CASE 3.—A man aged 36, given two metrazol shocks for a depressive psychosis, had severe pain in the upper part of the back, aggravated by coughing, sneezing and deep breathing, after the second treatment. At physical examination he was tender along the muscles of the back on both sides of the spinous processes from the fourth to the tenth thoracic vertebra. The spinous processes were tender, and pain was produced on contraction of the serratus magnus and the trapezius muscles bilaterally. The impression given was that these muscles had been strained. Short wave heat therapy and a tight chest binder with shoulder straps were used. The patient returned Feb. 21, 1939, with the pain in the back unchanged. Roentgenograms disclosed moderate compression fractures of the sixth and seventh thoracic vertebral bodies (fig. 3). A Bohler hyperextension plaster cast was applied, with relief of symptoms. Subsequent studies of the blood showed 11.9 mg. of calcium and 3.5 mg. of phosphorus.

CASE 4.—A man aged 31, with reactive depression of nine months' duration, was given three metrazol shocks. Persistent pain in the back followed treatment, with radiation around the right side of the chest. Roentgenograms disclosed slight compression of the fifth and sixth thoracic vertebral bodies, with a small chip fracture (fig. 4).

CASE 5 (Dr. W. L. Sucha).—A man aged 53 was treated for paranoid schizophrenia by means of metrazol shock. During the sixth shock, Dr. Sucha heard a crunching sound in the pelvis. Roentgenograms disclosed an intrapelvic dislocation of the left femoral head secondary to a fractured acetabulum, a duplicate of that shown in figure 2.

CASE 6 (Dr. J. W. Martin).—A woman aged 42 was having her twentieth metrazol shock for a manic-depressive psychosis when a soft grating was heard, apparently coming from the right shoulder. Roentgenograms disclosed an avulsion fracture of the lesser tuberosity (fig. 5).

CASE 7 (Dr. W. L. Sucha).—A woman aged 49 during a second metrazol shock, Aug. 17, 1939, sustained a supracondylar fracture of the femur (fig. 6).

CASE 8 (Dr. W. L. Sucha).—A man aged 23, six months before treatment had sustained a severely comminuted fracture of the elbow. During shock treatment April 15, 1938, the elbow was refractured.

Fig. 3 (case 3).—Moderate compression fractures of the sixth and seventh thoracic vertebral bodies.

One might well ask Is some predisposing factor, unrecognized at present, complicating the picture in shock therapy? A plausible consideration is the possible presence of bone atrophy. Steiner[9] mentioned two middle-aged men in whom multiple pelvic fractures developed spontaneously on the basis of starvation osteomalacia. It is not unreasonable to expect moderate dietary difficulty in psychotic patients, with resultant osteoporosis, but there was no such provoca-

9. Steiner, P.: Hungerosteomalazie mit multiplen spontanfrakturen des Beckens, Wien. med. Wchnschr. **77**: 972 (July 16) 1927.

tive factor in any of the reported cases, as all the patients were well nourished. In cases 2 and 3, in which the value for blood phosphorus was below the adult minimum, osteoporosis may have been present and have contributed toward the severe acetabular shattering.

To relieve the body of severe stresses to which it is subjected during a therapeutic convulsion, we have instituted the following prophylactic treatment to remove the potential forces of the lower extremity and spinal flexor muscular contractions: From thirty minutes to an hour before injection of metrazol, 10 mg. of pontocaine hydrochloride[10] or 100 mg. of procaine hydrochloride dissolved in 4 cc. of spinal fluid obtained by puncture between the first and second lumbar vertebrae by means of a 22 gage needle is slowly reinjected intraspinally.

Fig. 4 (case 4).—Slight compression of the fifth and sixth thoracic vertebral bodies, with a small chip fracture.

This transient anesthesia, with complete sensory and motor paralysis of all thoracic and lumbar segments, wears off in about an hour after the convulsion. The convulsive shock ensues without contraction of the anesthetized areas. In order to reinforce the cerebral anoxic affect we prolong the period of apnea by holding the mouth and nose tightly closed for from thirty seconds to a minute after the tonic spasm is over. Since shock therapy is given every three days for about five to eight injections in the treatment of affective psychoses, the spinal anesthetic offers no serious drawback to the treatment. With the spinal and lumbar muscles relaxed, one then has only to pay careful attention to the upper extremities, and at the onset of the tonic spasm both arms are held adducted against the wall of the chest.

Fig. 5 (case 6).—Avulsion fracture of the lesser tuberosity.

For schizophrenic patients who require a larger number of metrazol shocks we have not as yet experienced mechanical complications with the technic we employ. We first induce hypoglycemic shock, at the onset of coma administer metrazol and immediately follow with the administration of hypertonic dextrose solution. The tetanic spasm seems less severe after insulin shock has set in, and this may very likely be a factor in preventing fractures with this group of patients.

Because of these hazards of treatment and for other reasons mentioned elsewhere by one of us,[7] we are still inclined to disagree with those who recommend this type of therapy for home, office or general hospital management. Only in a well equipped psychiatric department under most careful supervision can it be administered successfully and some of these serious complications be prevented.

10. Supplied by the Winthrop Chemical Company, Inc., for investigative purposes.

CONCLUSIONS

1. The muscular contractions of shock therapy may be classed with those of tetanus in their severity and subsequent pathologic change. We believe that future studies will reveal a higher incidence of fracture complications, especially spinal, than has previously been suspected.

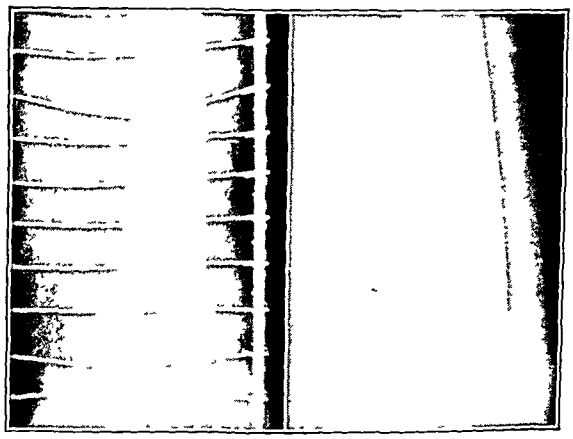

Fig. 6 (case 7).—Supracondylar fracture of the femur.

2. Preliminary studies of the blood calcium and phosphorus would indicate the presence of osteomalacia in advanced stages only.

3. Persistent pain in any region of the body following shock therapy should call for immediate roentgenologic examination.

4. Spinal anesthesia induced prior to shock therapy prevents severe fractures of the spine and lower extremities. Because of the present hazards of convulsive shock therapy, its use should be restricted to well equipped psychiatric departments.

527 Medical Arts Building.

Manson and Winged Insects.—The life of Manson may well be regarded as an epoch, for he initiated a new era in medicine, viz., the association of the spread of disease in man with the agency of winged insects. This was such a revolutionary conception that it could only be gradually accepted by the majority of the medical profession, and still more gradually by the lay public. It may be argued that there were others before the subject of this biography who had in some hazy way associated certain diseases with the presence of insect life, but there it remained more as a nebulous idea than as a concrete and proven fact. Manson did more than this: he started and fathered the teaching of a new department of medicine—Tropical Medicine—of which he is now justly regarded as the greatest master of all time.—Power, Sir D'Arcy: British Masters of Medicine, Baltimore, William Wood & Co., 1936.

PREOPERATIVE ROENTGEN DIAGNOSIS OF GALLSTONE ILEUS

ROBERT M. LOWMAN, M.D.
AND
EGON G WISSING, M.D.
BOSTON

Preoperative roentgen diagnosis of intestinal obstruction due to gallstone has only rarely been recorded in the literature. In a series of 3,064 cases of intestinal obstruction reported by the British Medical Association [1] the incidence of gallstone as the causative factor was twenty-eight cases, or 0.9 per cent. In none of these cases was a diagnosis reported as having been made preoperatively. Wilms [2] reviewed the available statistics in Germany and found gallstones as the cause of obstruction in 2.1 per cent of cases. Sante [3] found four cases in 287 of obstruction of the bowel. The operative mortality varies between 40 and 50 per cent, and most surgeons believe that delay in operating is largely responsible for the high death rate. A review of the literature reveals only seven cases [4] in which a definite diagnosis of gallstone ileus was established prior to operation; these are listed in the accompanying table.

Preoperative Roentgen Diagnosis of Gallstone Ileus

Author	Sex	Age	Symptoms	Roentgen Examination (A) Following Barium Sulfate Meal (B) No Contrast Medium Given	Operation
Lüdin	♀	70	Pain, vomiting	(A) Gastric retention, distention of small bowel, opaque oval shadow corresponding to gallstone seen in small bowel	Jejunolithotomy; gallstone 4.5 cm. in diameter noted in lower end of small bowel, autopsy showed a cholecystoduodenal fistula
McWhorter	♀	63	Epigastric pain, vomiting	(B) First examination: small, spherical, dense shadow with a faint oval shadow about it	Cholecystectomy; cholecystoduodenal fistula noted, no gallstones seen
				Second examination, after increase in severity of symptoms: the same shadow noted previously in the gallbladder region was seen on the right, in the region of the ileocecal valve; bowel distention was noted	Enterostomy; gallstone in region of ileocecal valve
Brocq, Brodin and Aime	♀	50	Abdominal pain and soreness, vomiting	(A) Normal stomach, peculiar bulb with no contractive power, barium sulfate did not fill bulb uniformly but only about the periphery	Enterostomy with extraction of calculus; death 1 day later; cholecystoduodenal fistula
Crane	♂	80	Pain, vomiting, abdominal distention	(A) Large calculus in region of duodenojejunal junction, causing distention of duodenum; contrast medium noted in gall bladder, common duct and bile duct	Jejunolithotomy; gallstone removed from intestine, death resulted four days later
Kaiser	♀	55	Obscure abdominal pain	(A) Fluoroscopy showed dilated loops of small bowel filled with barium sulfate, with a filling defect in the duodenal bulb	Jejunolithotomy; stone in distal portion of jejunum; death four days later; autopsy showed cholecystoduodenal fistula
Schele	♂	64	Anorexia, distention, pain, vomiting	(A) Delayed emptying, gastric retention, duodenal dilatation; contrast medium noted in biliary ducts and gallbladder, gallstone noted in region of duodenojejunal flexure	Jejunolithotomy; roentgen examination after operation showed barium sulfate and air in gallbladder
Safwenberg	♂	79	Abdominal pain, vomiting, indigestion	(A) Fluid level, distention of small bowel, evidence of gallstone in region of small bowel surrounded by opaque medium	Enterostomy, autopsy showed cholecystojejunal fistula
	♀	60	Pain in region of kidney, vomiting	(B) Stone with concentric ring shadow lying in distended jejunal loop	Enterolithotomy; death two days later

In cases of intestinal obstruction running an obscure course, x-ray examination may often be advantageously undertaken in order to establish the diagnosis. Numerous investigators advocate x-ray examination in all cases of obstruction except those in which there is diffuse peritonitis. Thus fluoroscopic examination and a film of the abdomen in the erect position may furnish evidence of fluid levels or abnormal collections of gas. Ochsner [5] pointed out that great caution should be exercised in the oral administration of barium sulfate because of the danger of making the ileus more acute. The x-ray scout film may show the stone early, before distention of the loops of bowel has occurred. Isolation and identification of the shadow caused by the stone after distention is difficult, so that in most cases only a diagnosis of ileus of the small bowel can be made. Bécheț,[6] Guillemin,[7] Santy,[8] Vidgoff [9] and Moulonget [10] have described cases in which x-ray examination established a diagnosis of ileus and in which at operation or autopsy impacted gallstones were seen in the intestine. In addition to the usual signs of ileus, the barium sulfate meal may demonstrate the fistulous tract between the gallbladder and the bowel.

REPORT OF CASE

A white woman aged 67, admitted to the Massachusetts Memorial Hospitals March 28, 1938, complaining of nausea and vomiting for six months, stated that she had had "gallstones" for twenty-seven years. About eleven years before she had had two severe attacks of jaundice with pain in the right upper quadrant. For the past six months she had noted epi-

gastric distress with the taking of food, accompanied by marked gastric eructations. Vomiting occurred every two or three days, with ejection of large amounts of food containing remnants of the previous day's meal. The patient had lost 30 pounds (13 Kg.) during the last six months.

March 23 epigastric distress became markedly increased and in the evening there was a gradual onset of pain in the right upper quadrant, radiating to the right flank and thigh. The pain increased in intensity and became so severe as to cause the patient to cry out in agony. During the night the pain diminished, the right upper quadrant and thigh, however, remaining quite tender. This episode was followed by nausea and continued vomiting of bile, mucus and fecal material. No food could be retained. In the morning March 27 and 28 there were repeated attacks of cyanosis and dyspnea.

On admission the patient appeared rational, well developed, well preserved, obese but dehydrated, and acutely ill. She was very restless and her reflexes were hyperactive. Trousseau's

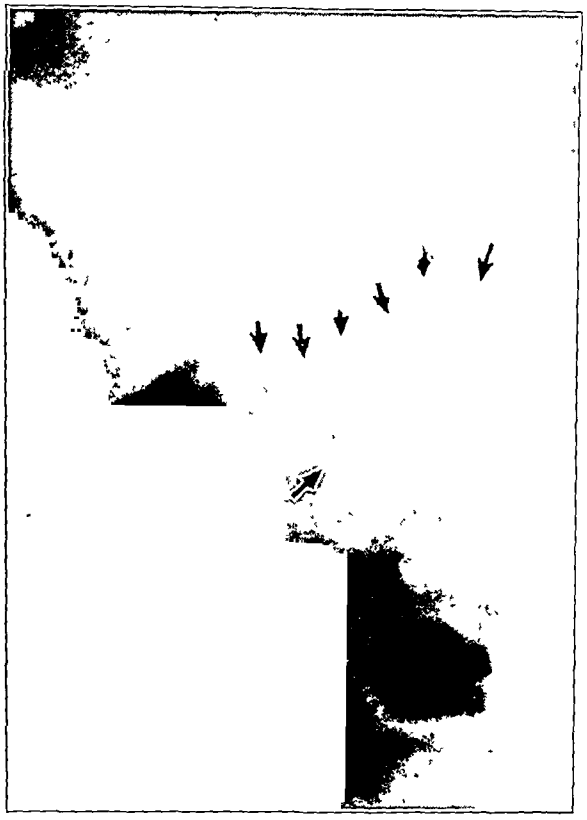

Fig. 1.—Upper right quadrant, showing gallstones. Note the gas surrounding the large stone (arrows).

sign and a carpal spasm were elicited when the cuff of the blood pressure apparatus was inflated about her arm. The respirations were slow and shallow and the lips were cyanotic. The blood pressure was 80 systolic and from 30 to 40 diastolic. The heart sounds were poor. The abdomen was obese but was not distended.

The patient was given 2,000 cc. of saline solution, and Wangensteen suction was begun. X-ray examination showed several more or less opaque circular shadows in the right upper quadrant which had the definite appearance of gallstones. The stomach showed a moderate amount of gas in the fundus, the remaining contour being defined by a small amount of gas. The large bowel could be identified by its gas content but no loops of small intestine were visualized, the absence of gas in the duodenal loop being particularly significant. Careful inspection of the film showed the gallstones in more or less compact formation with a faint halo of gas, indicating that these were contained in the same viscus. The diagnosis based on x-ray examination was obstruction of the duodenum by gallstones.

An operation performed March 31 by Dr. Milo C. Green revealed multiple stones in the fundus of the gallbladder, one large stone lying transversely in the first portion of the duodenum, approximately 1¼ inches from the pyloric sphincter. The stones were removed. After a posterior gastrojejunostomy

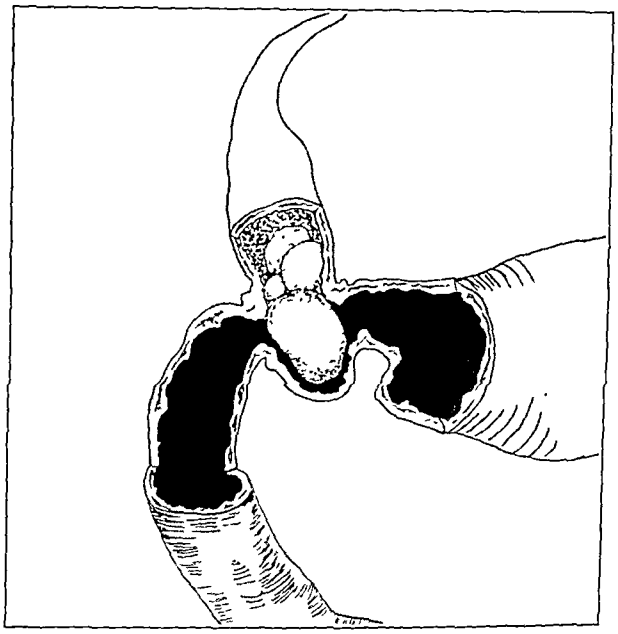

Fig. 2.—Stomach obstructed by a large single stone which has passed through the perforation in the gallbladder into the duodenum.

the gallbladder was freed from its firm adhesions to the liver. Through the stoma of the cholecystoduodenal fistula, four faceted gallstones were removed from the gallbladder and the

Fig. 3.—The stones after removal.

large single stone was extracted from the duodenum. The cholecystoduodenal fistula was then reconstructed.

The postoperative convalescence was uneventful except for the occurrence of a mild phlebitis of the left leg, which disappeared in five days.

While intestinal obstruction due to gallstones is less common than other forms of ileus, the possibility must be borne in mind since successful operation depends on early diagnosis. It is our opinion that in most cases of obstruction due to gallstones these are calcium stones. This can best be explained by the fact that perforation of the gallbladder is a result of chronic involutionary changes, during which there has been sufficient deposition of calcium to render the stones radiopaque.

The distribution of gas shadows is important. Gas proximal to the stone with no gas in the lumen distal to it should be considered strong evidence of mechanical obstruction due to stone.[11]

MASSIVE PULMONARY COLLAPSE TREATED WITH ARTIFICIAL PNEUMOTHORAX

REPORT OF A CASE

HAROLD G. JACOBSON, M.D.
SAMUEL GENDELMAN, M.D.
AND
DOUGLAS GOLDMAN, M.D.
Clinical Director of Longview Hospital
CINCINNATI

Since William Pasteur[1] first described pulmonary atelectasis following diphtheria and then discussed its occurrence following surgical procedures[2] massive collapse of the lung has been frequently recognized by the medical practitioner.

The causes, symptoms and signs of this condition are well known and adequately described in the modern textbooks. The prognosis as to life when the condition is uncomplicated is usually excellent, although death may occur in debilitated subjects if collapse occurs in more than one lobe or bilaterally.[3] The greatest danger in pulmonary atelectasis is the secondary development of pneumonia. Since pneumonia in itself is a serious disease, it becomes important either to prevent pulmonary atelectasis or to relieve it as soon as possible when it does occur. In this brief report we shall confine ourselves to the therapy of the condition after it has occurred and make no mention of prophylaxis.

The methods of therapy usually employed at present, for postoperative collapse particularly, are apparently fairly effective. All more or less aim to release the secretions that may be obstructing the bronchi of the affected lung. These therapeutic measures consist of (1) loosening of any tight dressings, (2) induction of deep breathing with 10 per cent carbon dioxide in oxygen every fifteen or thirty minutes, (3) induction of hard coughing with the affected side uppermost by severe manual percussion of the chest, (4) postural drainage of the bronchus by assumption of a 10 per cent Trendelenburg position of the bed for from fifteen to thirty minutes every three or four hours,[4] (5) intravenous administration of a 10 per cent solution of sodium iodide to aid in the loosening and expulsion of bronchial secretions, (6) bronchoscopic treatment to remove any bronchial plug[5] (a difficult, dangerous and unpractical procedure in inexperienced hands) and rolling of the patient back and forth on the unaffected side[6] (which is quite difficult for an already acutely ill patient and has not proved overly successful).

The possibility of inducing artificial pneumothorax on the affected side in treating pulmonary collapse was first suggested by Elliott and Dingley[7] in 1914. At that time they wrote: "It is conceivable that the worst cases of cyanosis and pain might be relieved by an intrapleural injection of oxygen in order to restore the balance of volume and push back the displaced heart and the overdistended lung. Fortunately, these urgent cases are rare, and we have had no occasion to try this method since the possibility of such a line of treatment occurred to us." Unfortunately, nothing was done to carry out this far sighted suggestion until 1927, when Gordon Wilson,[8] speaking on atelectasis at the American Climatological and Clinical Association, suggested partial pneumothorax as an aid in diminishing an elevated negative pressure or making a negative pressure positive to assist in forcing an obstructing agent out of the bronchus. The entire procedure was placed on a more rational basis when it was learned shortly after that patients with pulmonary collapse characteristically had an increased negative pressure in the pleural cavity of the affected side.

Elkin[9] in 1927 presented three cases of atelectasis all with an increased negative intrapleural pressure on the side affected, but did not resort to introduction of air for treatment. In 1928 Habliston[10] reported four cases of atelectasis due to different causes with increased negative pressure in the pleural cavity on the affected side. (One case was again reported, in 1930, by Ashbury.[11]) This important accompaniment of atelectasis was substantiated later by Coryllos and Birnbaum.[12]

Fig. 1.—View taken Nov. 8, 1937.

The average normal intrathoracic pressure is approximately minus 70 mm. of water on inspiration and minus 40 mm. of water on expiration. Aron[13] found in thirty-six normal adults an average pressure of minus 79.6 mm. of water on inspiration and minus 34.29 mm. on expiration. The approximate average intrathoracic pressure on the atelectatic side in the cases reported in the literature is from minus 150 to minus 250 mm.

11. Since the completion of this paper, three additional cases have been noted in the literature in which the preoperative diagnosis of gallstone ileus was made.

of water on inspiration and from minus 75 to minus 150 mm. on expiration. In one of Habliston's cases the pressure was minus 442 mm. of water on inspiration and minus 337 mm. on expiration.

Habliston used artificial pneumothorax on the affected side in two of his reported cases, with quick relief in both and a startling result in one, in which an intrabronchial tumor causing the collapse was expectorated two days after air was injected into the pleural cavity. In the other case the condition was due to pulmonary tuberculosis. This constituted the first report in the literature of the successful treatment of massive collapse by artificial pneumothorax. In 1930 Moorman [14] reported a case of pulmonary collapse in a white girl following an abdominal operation, quickly relieved by the introduction of 300 cc. of air into the pleural cavity on the affected side. Schindler and Gnagi [15] in 1938 reported a case of massive collapse of the lung in a child of 12 following an appendectomy, with complete and almost immediate reexpansion of the lung following the introduction of air into the pleural cavity on the affected side. As far as we can tell there are no other cases on record wherein this procedure was attempted.

Fig. 2.—View taken Oct. 14, 1938, at the time the diagnosis of massive collapse of the left lung was made.

REPORT OF CASE

M. M., a Negro man aged 41, had been in this hospital continuously since October 1935. The diagnosis was far advanced pulmonary tuberculosis, dementia paralytica and aneurysm of the thoracic aorta (fig. 1). Until the present incident he had been doing fairly well with bed rest and antisyphilitic therapy.

Fig. 3.—View taken Oct. 16, 1938, after reexpansion of the lung.

Early in the evening of Oct. 14, 1938, he suddenly became acutely dyspneic without apparent pain. At physical examination he was seen to be fairly well nourished, was sitting up in bed, was acutely dyspneic and was obviously in distress. The temperature was 100 F., the pulse rate 120, the respiratory rate 46 and the blood pressure 100 systolic, 75 diastolic. There was moderate cyanosis of the nail beds and lips. There was no pulsation of the jugular vein and no dependent edema, and the liver was not palpable.

The relevant physical signs were confined to the chest. There was limited excursion of the entire left side of the chest, with dulness to percussion over the whole left lung. The breath sounds were absent on the left. The right side of the chest was resonant to percussion, and the breath sounds came through strongly. The left border of the heart was found to be in the sixth interspace at the left midaxillary line by palpation of the maximal apical impulse. The right border could not be outlined by percussion. The heart sounds were of fair quality and the rhythm regular, with a rate of 120 a minute at the apex and wrist. There was no murmur audible. A diagnosis of massive collapse of the left lung was made. This was corroborated immediately by fluoroscopic and radiographic examination (fig. 2). The shift of the mediastinum to the left was readily apparent. It was thought that the collapse of the lung was due to obstruction of the left main stem bronchus by the aortic aneurysm, although pulmonary tuberculosis as an etiologic factor could not be ruled out.

The patient was closely watched for twelve hours. On the morning of October 15 he was worse, with increasing dyspnea. The temperature was 100 F., the pulse rate 130 and the respiratory rate 48. The chest signs were essentially the same as before. At this time it was decided to carry out artificial pneumothorax on the affected side. With a standard pneumothorax machine, 500 cc. of air was injected into the left pleural cavity at an approximate rate of 50 cc. a minute, with no immediate untoward result. The initial pressure was minus 160 mm. of water on inspiration and minus 80 mm. on expiration. At the completion of the procedure the average pressure was plus 15 mm. of water.

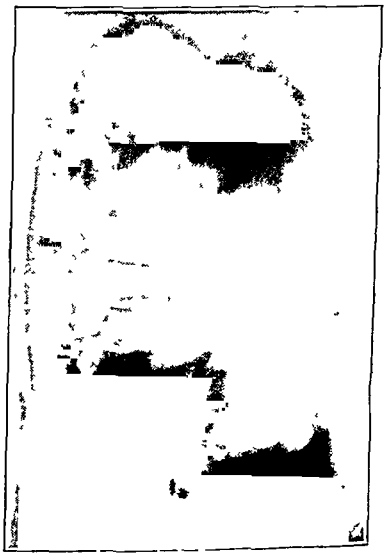

Fig. 4.—Lateral view, showing pneumothorax clearly; taken when figure 3 was taken.

Several hours later the patient was somewhat improved, and the evening of the same day saw a lessening of the dyspnea and almost complete disappearance of the cyanosis. The next morning, October 16, he was seen lying quietly in bed in apparent comfort with no dyspnea or cyanosis. The temperature was 98.6 F., the pulse rate 100 and the respiratory rate 22. The left side of the chest was now resonant to percussion, while the breath sounds came through strongly with many moist rales. The right side was resonant to percussion, with normal breath sounds. The left border of the heart could now be outlined 10 cm. to the left of the midsternal line. The heart sounds were unchanged. Fluoroscopic and radiographic examination of the chest was repeated, and the left lung was seen to be almost completely reexpanded, with a resultant shift of the mediastinum back to its normal position (fig. 3). There was an area of pneumothorax on the left behind the aneurysm (fig. 4).

November 3 the patient was in good condition, with no recurrence of his atelectasis.

COMMENT

It is obvious that in relieving this patient's atelectasis we have not brought about a change in his underlying condition, but we feel that we have prolonged his life, for he might have died as a result of persistent massive pulmonary collapse. Although the result in this case might be called somewhat startling, its value lies in demonstrating the possibility of using artificial pneumo-

14. Moorman, L. J.: Massive Collapse of the Lung with a Case Report, Ann. Int. Med. 3: 1024 (April) 1930.
15. Schindler, J. A., and Gnagi, W. B., Jr.: Postoperative Pulmonary Atelectasis: Report of a Case Treated by Artificial Pneumothorax, Ann. Int. Med. 11: 2276 (June) 1938.

thorax generally for massive collapse of the lung. The method is easy to carry out and mechanically rational. Since all patients with pulmonary atelectasis show increased negative intrapleural pressure, it seems likely that the cyanosis and dyspnea are due primarily to a displacement of the heart and great vessels and to an acute overdistention of the unaffected lung. In cases of atelectasis following abdominal operations, presumably resulting from bronchial obstruction, the marked increase of intrapleural negative pressure can serve only to draw the entire obstructing medium more firmly and deeply into the bronchus, thus perpetuating a vicious cycle. Introducing air into the pleural cavity serves to break the cycle, tends to push the mediastinum back to its original position and probably would enhance the expulsion of the obstructing medium (see Habliston's case of intrabronchial tumor expectorated on the second day following artificial pneumothorax).[10]

Mistakes.—An investigator who draws false conclusions early in his research may see the whole structure of the work topple, for here conclusions follow in sequence and an early fallacy affects all; moreover, his work is placed on record and is submitted to close and critical supervision. To a physician, mistakes, if not too frequent, are of little consequence—they are indeed inevitable; they do not shake self-confidence as they do in the case of the research worker—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

PERFORATING ULCERS OF FEET, WITH OSSEOUS ATROPHY

IN A FAMILY WITH OTHER EVIDENCES OF DYSGENESIS (HARELIP, CLEFT PALATE): AN INSTANCE OF PROBABLE MYELODYSPLASIA

LEANDRO M. TOCANTINS, M.D.
AND
HOBART A. REIMANN, M.D.
PHILADELPHIA

An arresting example of the influence of heredity in disease is the development of the same chronic pathologic process in two or more members of a family when they reach a specified age. The family in the two cases herein reported furnishes such an example.

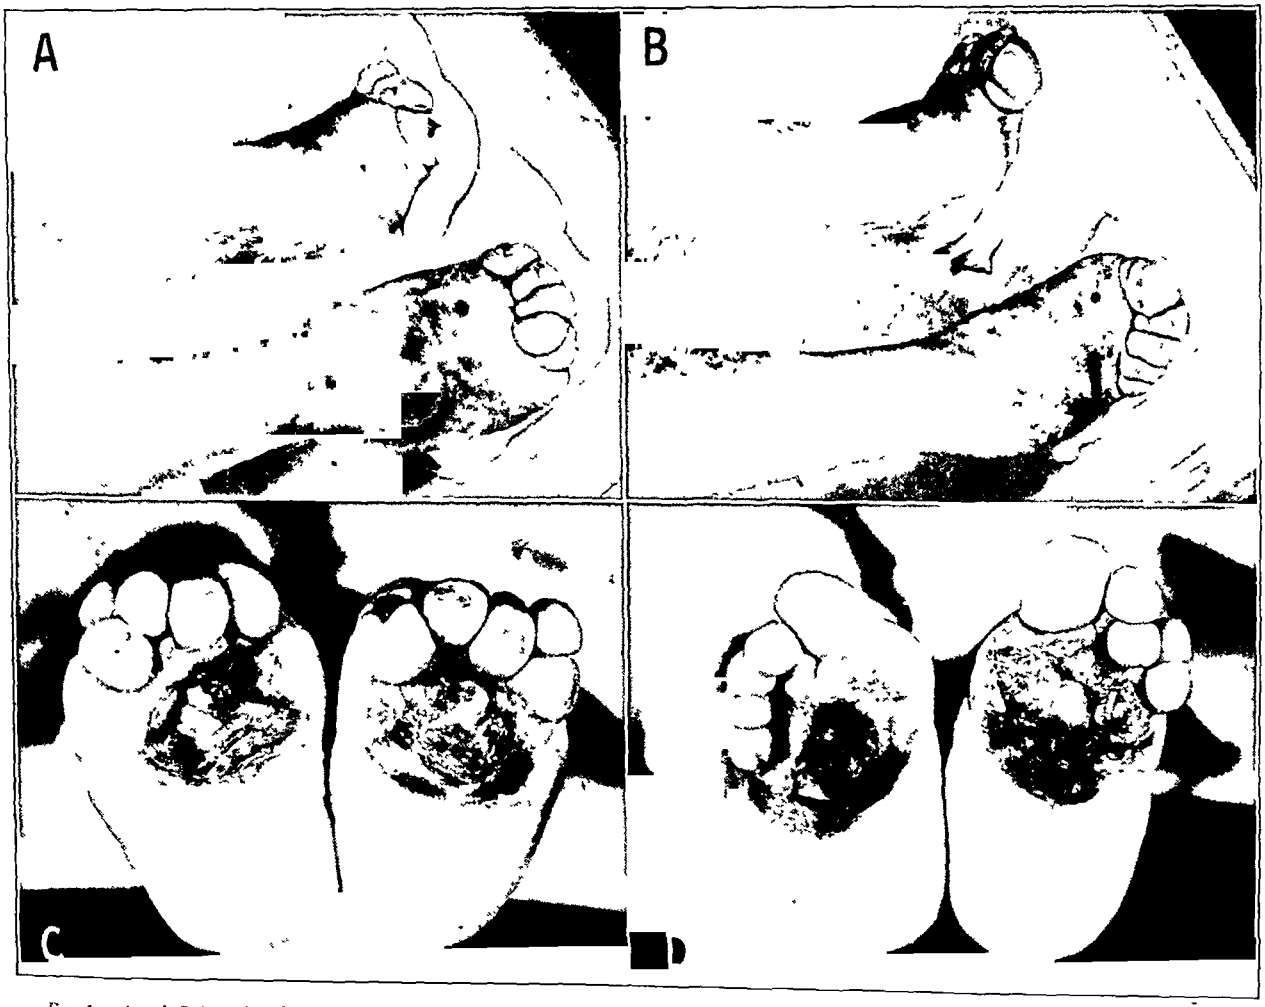

Fig. 1.—*A* and *C*, lateral and plantar aspects of the lower extremities of R. D., *B* and *D*, similar aspects of the lower extremities of H. D.

In October 1937 Dr. J. Torrance Rugh of the department of orthopedics received a letter from two young men claiming that they "were very interesting cases" and would like to be studied and treated at this hospital. Through the courtesy of Dr. Rugh the patients, once admitted, were transferred to the medical service, where the following studies were conducted. Only the two principal cases will be dwelt on at length and simple mention made of relevant points in the histories of other members of the family.

Aided by a grant from the J. Ewing Mears Research Fund.
From the Department of Medicine, Jefferson Medical College and Hospital.

REPORT OF CASES

CASE 1.—*History.*—H. D., a white man, single, aged 27 (D-17 on the pedigree chart), with no occupation, at the age of 18 noticed a small blister which had appeared on the sole of the right foot followed within two weeks by one on the sole of the left foot. The blister broke down, an ulcer formed and enlarged and a piece of bone was extruded about a month after the onset. He wore at this time a size 5½ shoe. He could then distinguish between heat and cold on the skin of the feet but, as the process spread, sensation for pain, heat and cold disappeared; if he persisted in walking while sequestrums were extruding he felt some discomfort. The loss of sequestrums continued at about the rate of two bony spicules a month. The feet began to shorten and become rigid and apparently fixed at the ankle. At present if he does not use his feet for several weeks the ulcers eventually become smaller and heal over the entire surface; walking about for a few days, however, is enough to start the ulcerative process over again. The skin of the feet perspires excessively. His general health has been excellent and outside of this disability he has no other complaints. For a time he did amateur boxing, but the necessity of resting every few weeks to allow the ulcers to heal has restricted his activity considerably.

Examination.—The patient is an intelligent person with good general muscular development. In the mouth there is an overriding canine tooth on the left upper maxilla. Examination of the chest and abdomen is negative. There is slight cyanosis of the finger tips. Arm and forearm reflexes are prompt and active and sensation is normal. Distal to both knees there is a dusky pink, patchy discoloration and scaliness of the skin. The lower third of both legs, as well as both feet, are covered with fine perspiration. Both feet are short, in the anterior half especially, the toes appearing to spring directly from the middle portion of the foot without the intervening metatarsals (fig. 1 *B*). This gives the foot the appearance of a horse's foot ("pferd fuss" of Bruns). About the base of the first toe, the skin is folded over the invaginated toe. On the sole of each foot there is a punched out ulcer with a moist granulating base and sharply limited margins measuring 5 by 2 cm. on the right foot and 6 by 3 cm. on the left (fig. 1 *D*). The skin over both knees and on the soles is loose and wrinkled, more markedly on the left side. Both dorsalis pedis arteries are easily palpated, the pulse being full and forcible and apparently equal on the two sides. There are no muscular atrophies or contractures and the muscular strength is normal. There is hypesthesia to touch reaching almost anesthesia over the five toes bilaterally. Sensation of pinprick is almost lost over the feet and is felt more and more up toward the thighs, where it is still slightly impaired. Temperature sense (heat and cold) begins to be impaired just distal to both knees and is completely lost distally to the middle of both legs. Vibratory sense is intact, but the sense of position of the toes is lost. The corneal, laryngeal and pharyngeal reflexes are equal and active. The deep reflexes are equal and hyperactive (+4). The abdominal, cremasteric and achilles tendon reflexes are absent. There are no demonstrable pathologic reflexes or ankle clonus. Oscillometric readings are normal in both thighs and legs; in the feet they are above normal. The temperature, pulse and respiratory rates are normal. The basal metabolic rate is +11; urinalysis is negative; a blood count revealed 87 per cent hemoglobin, 4,810,000 erythrocytes and 11,900 leukocytes, with a normal differential count. Wassermann and Kahn reactions of the blood are negative. The blood sugar is 75 mg. per hundred cubic centimeters of blood, nonprotein nitrogen 24.4 mg., calcium 11.2 mg., phosphorus 3.7 mg. and phosphatase 3.8 mg.

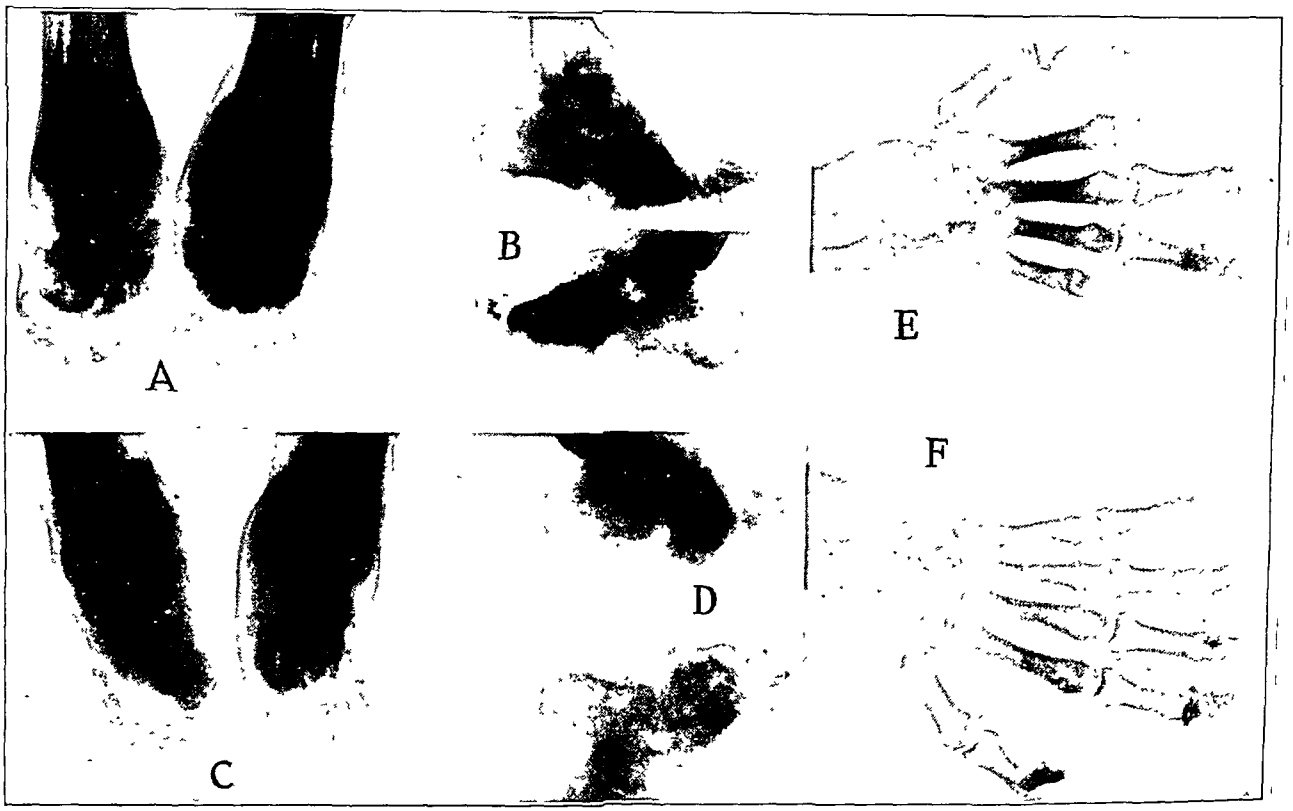

FIG. 2.—Appearances of feet of R. D. (*A* and *B*) and of H. D. (*C* and *D*) and of the right and left hand (*E* and *F*) of A. D., the father of the two boys.

Roentgenologic examination[1] revealed a spina bifida occulta involving the upper segment of the sacrum. When iodized oil was injected into the spinal canal, no obstruction to the flow of oil or any other abnormality was demonstrated. The bones of the skull have a normal appearance and so have the paranasal sinuses, clavicles, scapulas, ribs, lungs and the lumbar vertebrae, the bones of the pelvis, the radiuses, ulnas, carpals and all the phalanges of the fingers. The sella turcica is a little flattened.

The pelvis and calices of both kidneys as visualized by injection of a radiopaque substance are normal. Metatarsals and

1. The roentgenologic examinations were conducted under the direction of Dr. John Farrell. A neurologic examination of three of the patients was performed by Dr. J. C. McNerney.

phalanges are very much deformed and largely destroyed (fig. 2 *C* and *D*). The fibulas show a little roughening and thickening along their margins.

CASE 2.—*History.*—R. D., a man aged 24, single (D-18 on the pedigree chart), brother of patient 1, at the age of 17 noticed a small blister on the sole of his foot (he is uncertain which foot). It was soon followed by a blister on the other foot, ulceration and extrusion of sequestrums. The rest of the history is essentially the same as that of his brother.

Examination.—This patient is slightly thinner than his brother but of fairly good general development. There are no significant abnormalities in the head, neck, chest and abdomen except for a soft systolic murmur at the apical area of the heart. There is cyanosis and curving down of all finger nails and slight clubbing of the fingers. The skin of the lower third of the legs and feet has a dusky hue and is scaly and covered with beads of perspiration in the dorsum of the foot. The legs and feet (fig. 1 *A* and *C*) have, as a whole, an appearance almost identical with those of his brother. The plantar ulcer on the right foot measures 3.5 by 3.5 cm., while that on the left measures 5 by 5 cm. The dorsalis pedis pulses are full and bounding on both sides. There are no muscular atrophies or contractures, and the muscular strength is normal. Sensation to touch is lost over all the toes and is impaired up to a level just above the knees. There is hypesthesia to pinprick from a level about the union of the upper and middle thirds of the thighs distally, ending with almost anesthesia over the toes. There is complete loss of temperature sense over the distal two thirds of the leg and the entire foot. The vibratory sense, bone, position and deep muscle sense are intact. All reflexes are present except the achilles tendon reflex. The deep reflexes are all hyperactive. No reaction of degeneration is present in the muscles of the legs or feet. The temperature, pulse and respiratory rates are normal. The blood pressure is 120 systolic, 68 diastolic. Oscillometric readings are normal for both lower extremities. The basal metabolic rate is +10. The blood count is 78 per cent hemoglobin, 4,500,000 erythrocytes and 8,900 leukocytes, with a normal differential count. The Wassermann and Kahn reactions of the blood are negative. The blood sugar is 79 mg., nonprotein nitrogen 25 mg., calcium 11.5 mg., phosphorus 4.1 mg. and phosphatase 5.2 units. Urinalysis is negative.

Roentgen examination shows normal bones of the skull, the pelvis, hands, femurs, radiuses, ulnas, paranasal sinuses and thoracic and lumbar vertebrae. The sella turcica is a little smaller than usual. The metatarsals are much deformed and largely destroyed and there are only remnants of the phalanges (fig. 2 *A* and *B*). The fibulas show a little roughening and thickening along their margins as though there were some periosteal involvement. An intravenous urogram and the injection of iodized oil in the spinal canal yielded negative results. There was no evidence of spina bifida.

There is only one more brother in a family of twelve children; T. D., aged 22 (D-19), leads an active life and has no complaints except that his feet get cold easily during the winter. There are no physical abnormalities except in the lower extremities; the skin over the inner surface of both legs has scaly patches, and the toes of both feet have a dusky bluish discoloration, most marked in the right third and left great toes. There are five black blister-like areas with a cornified base over the right third toe, plantar surface of the right fifth toe and both first metatarsals, and over the dorsal surface of the fourth left toe. There is a fine perspiration over both great toes. The left foot is colder than the right. Pulsation of the dorsalis pedis artery is full and equal. Light touch is felt over the entire skin surface bilaterally. There is hypesthesia to pinprick starting from about 3 cm. above the ankle distally on both sides, most marked over the first, second and fifth toes. Temperature sense is lost over all the toes. Muscle, bone, vibratory and position senses are intact. Superficial and deep reflexes are present, active

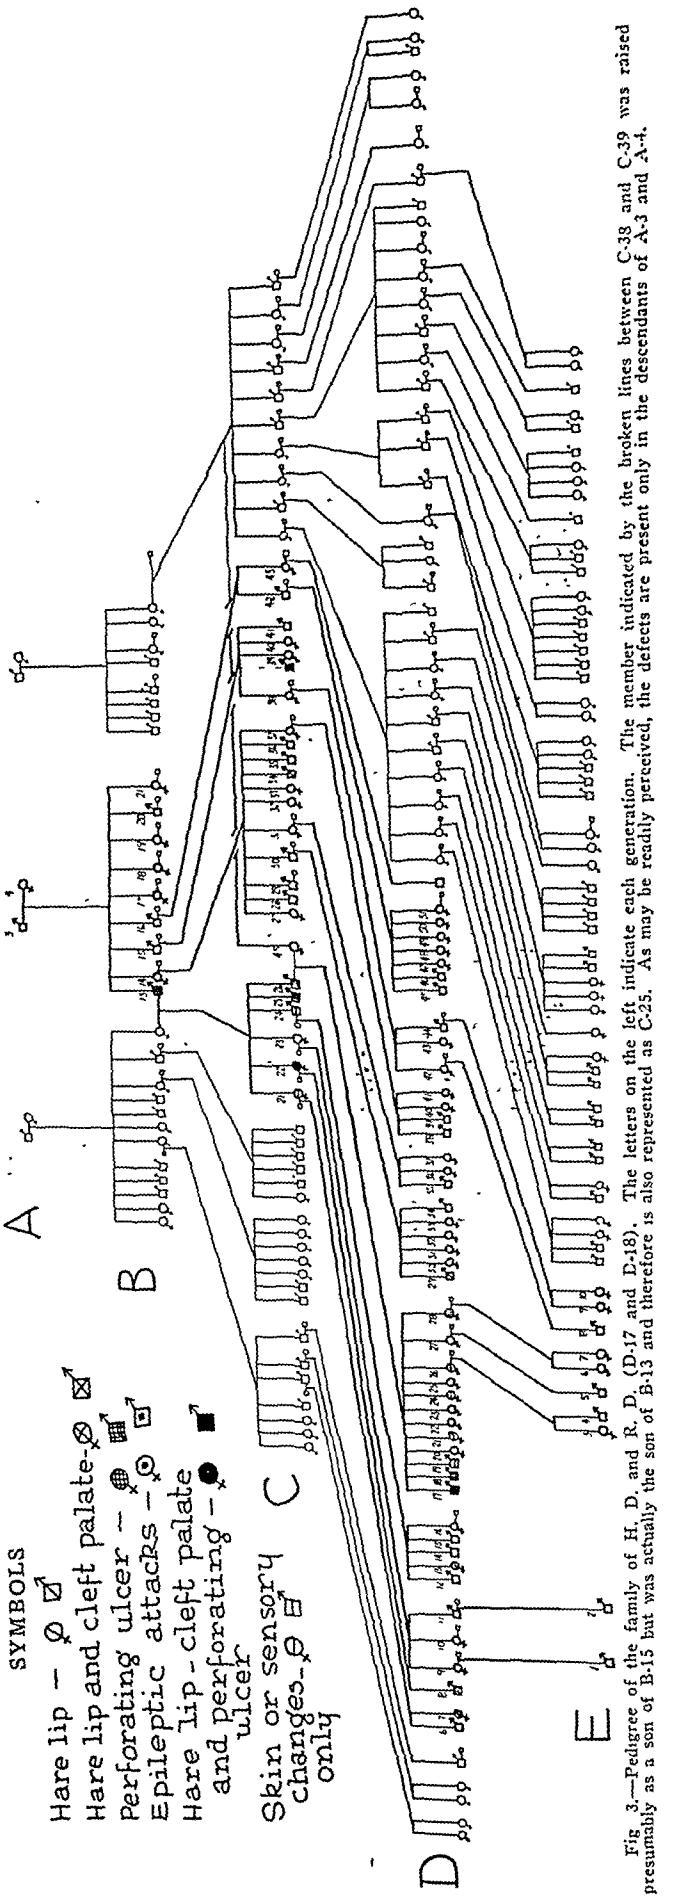

Fig. 3.—Pedigree of the family of H. D. and R. D. (D-17 and D-18). The letters on the left indicate each generation. The member indicated by the broken lines between C-38 and C-39 was raised presumably as a son of B-15 but was actually the son of B-13 and therefore is also represented as C-25. As may be readily perceived, the defects are present only in the descendants of A-3 and A-4.

and equal. The deep reflexes are all hyperactive (+ 4). Roentgenologic examination was negative except for the demonstration of a slight bifidity of the spine in the first sacral segment.

Of the nine sisters of these boys only one, E. S. (D-28) was known to have any ulceration of the feet. She died at the age of 25 of heart disease resulting from attacks of rheumatic fever. For six months before her death she had a large ulcer on the plantar surface of her toes similar to those on the feet of the two boys. Another sister, I. D. P., aged 30, married (D-26) had attacks of epileptic-like convulsions with transient loss of consciousness. Neurologic examination yielded negative results except for hyperactive deep reflexes and the presence of a small area of hypesthesia to touch and loss of temperature sense at the tip of the great toes. Of the seven remaining sisters, one, aged 23 (D-27) is in good health; she is married and has two boys one of whom (E-6) has a harelip; two sisters, one aged 15, J. D. (D-21) and another aged 14, M. D. (D-24) have hyperactive deep reflexes and dusky, cyanotic, scaly lower legs and feet but no other changes; the other four sisters are under 13 and when examined did not seem to have any abnormalities.

In the brothers' own generation there were no other members showing similar deformities. A paternal cousin, A. D., a girl aged 16 (D-13), had had several epileptic attacks and hyperactive deep reflexes. Another paternal cousin, G. D. McG., a girl aged 15, (D-7) was born with a harelip, which was later repaired successfully. At present she still has four deciduous teeth. Examination of the other cousins on the paternal side was negative.

In the third generation, the father of our two patients, A. D., aged 53 (C-26), had ulcers on both feet beginning at the age of 16. Spicules of bone discharged through these ulcers at intervals. In most respects the ulcers behaved as in his two sons. He continued to work hard throughout all this period; at times the ulcers became infected and cellulitis of the legs developed, with a high fever. At 35 the right foot had to be amputated above the ankle joint, and soon afterward the left foot was also amputated. All told, he has had six amputations in the lower limbs within the past ten years; he has also had ulcers in several fingers from which spicules of bone would extrude spontaneously or he would extract them himself with pliers. At the present time he has no index or little finger on the right hand and a few of the fingers appear shortened, as if some of the phalanges were missing. There is complete loss of temperature sense in the hands and forearms. There is marked hypesthesia in the hands extending up and gradually disappearing toward the shoulder. There is loss of temperature and pain sense below the knee to the end of the stump, which extends about 20 cm. below the knee and is ulcerated in several areas. On roentgenologic examination there is no evidence of spina bifida. The lumbar vertebrae and bones of the pelvis are normally developed. The distal and part of the middle phalanx of the fourth finger on the right hand are absent. Some changes are beginning to appear in the distal phalanx of the first finger of the same hand. In the left hand the distal phalanges of all fingers except the first and second are absent, and a good part of the middle phalanges are destroyed (fig. 2 *E* and *F*). The patient had a brother, C. D. (C-25), who also had ulcers on both feet from early adolescence and died at the age of 31 of diabetes. In the pedigree chart he is represented as a brother of A. D., though he was brought up as a son of A. D.'s paternal uncle. This accounts for the designation in the broken line of C-39 in figure 3. If C. D. had been a son of B-15 it would have been the only instance of the defect being transmitted through nonaffected parents. All members of the family who were interviewed were emphatic, however, in saying that C. D. was actually A. D.'s brother on his father's side, though born of a different mother. A younger brother of the father of our patients, D. D., aged 51 (C-24), has never suffered from any ulcerations; a physical examination of this man disclosed, however, definite impairment of the temperature and touch sense in a small area on the plantar and medial sides of the great toes, and hyperactive deep reflexes. All of this man's five children are in good health with the exception of one daughter, A. D. (D-13).

Of the three sisters of the father of our patients, one is apparently normal in every respect, her children and grandchildren also being normal. Of the other two, one A. D. McG., aged 42 (C-21), has hyperactive deep reflexes and small areas of loss of temperature and touch sense in the big toes. The other sister, L. D. J., aged 46 (C-22), is the only patient in the group who has all the defects. She was born with a harelip and complete cleft palate. For the past six years she has had several ulcers on the plantar surface of the left big toe and on the sole of the same foot. The ulcers are not as large as those of her nephews, but they have many of their external characteristics; they have healed and broken out several times in the past few years. Her deep reflexes are hyperactive and there is hypesthesia to touch, in some places amounting to anesthesia, with almost complete loss of temperature sense over all the toes and the plantar surface of the left foot and up to a point just below the ankle. In the right foot similar changes were noted, but over a more restricted area. She had only one child. This baby (D-8) was born with a harelip and complete cleft palate and died soon after birth.

In the second generation the only member of the family affected was T. D. Jr. (B-13), who died at the age of 42, the paternal grandfather of our two patients. According to information obtained from his wife, T. D. Jr. was the youngest in a group of nine children and the only one who had the disease. The ulcers on his feet began also in late adolescence and progressed to the point at which he had to have several toes and later both feet amputated. The man's wife states that just previous to the birth of her husband his father had contracted a venereal disease which she blamed for her husband's defect and accounted for the fact that previously born brothers and sisters had neither inherited nor transmitted the defect. T. D. Jr. had a sister, L. D. C., aged 70 (B-14), who had a baby (C-34) born with a harelip.

Of the first generation little is known. Our two patients and their grandmother had been told that our patients' great grandfather, T. A. D. (A-3), died at about the age of 80 and that just before he died gangrene of the feet developed. Up to that time, however, he had had no ulcers of the feet.

COMMENT

Tabes dorsalis, leprosy, syringomyelia and spina bifida occulta were considered as possibilities in the differential diagnosis. The strongly hereditary nature of the disease, the uniform date of onset, the absence of a positive history of contact and the negative sero-

logic examinations seem to exclude syphilis and leprosy from consideration. Though there are several instances of the appearance of syringomyelia in several members of one family, the fact that the disturbances first began in the lower extremities and the regularity of the age at which the onset of the disease took place seem to constitute points in favor of the hypothesis that the disturbance was due to an insufficiency or defect in the formation of the central nervous system rather than to an abnormal proliferation of neoplastic tissue in the cord. The trophic disturbances found in syringomyelia are so similar to those found in cases of spina bifida occulta that only the actual demonstration of the spina bifida can establish the diagnosis. All efforts made in that direction with our patients and their nonaffected relatives yielded, with one exception, a negative result. The exception (H. D., D-17 on the pedigree chart) did have, as shown by a roentgenogram, a spina bifida occulta; his brother, though similarly affected, did not have it. Such mild defects are, according to roentgenologists, too frequently noted in normal persons to warrant attaching much importance in this instance as being connected with the actual cause of the disease.

There are three outstanding features of this group of cases: (*a*) the hereditary trait, (*b*) the appearance of certain of the manifestations at about the same period of life and (*c*) the occurrence of developmental defects other than plantar ulceration in persons of the same family. One of the earliest reports of this condition is that by Bruns,[2] who described it as a familial symmetrical gangrene and arthropathy. The father and mother of the family he reported were over 70 years old and both healthy. There were five children, four boys and one girl. All were affected except the first born, a boy. The onset in all the affected children was at the same age, 17, with ulcers on the soles of both feet. Bruns attributed the trophic ulcers to a chronic progressive process in the lumbosacral region of the spine or in the cauda equina. One of his patients died as a result of infection but there was no autopsy.

The cases reported by Price [3] and Smith [4] are other examples of the same disturbance. Riley [5] reported a family in which there were several members, male and female, suffering with recurring ulcers of the feet appearing first at adolescence. In this family the mother was apparently the transmitter of this condition and more than half of her children, male and female, were affected.

Riley discusses at length the differential diagnosis between syringomyelia and myelodysplasia, a term advanced by Fuchs [6] to designate the clinical syndrome characterized by deformities of the feet with trophic and vasomotor disturbances, changes in the skin, spina bifida and syringomyelic sensory disturbances as well as other defects. The same condition has been described by Bremer [7] under the name "status dysraphicus" to indicate a disturbance in the closure mechanism of the primitive neural tube. In the group of defects listed by Bremer are also sternal malformations, kyphoscoliosis and other developmental anomalies. The association of harelip and cleft palate with trophic defects of the feet, present in our group, has not been recorded previously so far as we know; it fits well with the conception that the underlying disturbance must be referred to an embryologic maldevelopment. As pointed out by Riley,[6] syringomyelia is usually marked by a slow insidious progress with involvement and destruction of the ventral horn cells adjacent to the intramedullary neoplasm, while the syndrome of myelodysplasia presents a more static state of affairs with less evidence of progress, the outstanding disturbances being associated with trophic and vasomotor control. A differentiation between the two conditions from the clinical point of view may be impossible, and a description of pathologic changes in the cord in these cases is still wanting. Though familial and hereditary features are not uncommon in syringomyelia, they are not as outstanding as in the few reported cases of myelodysplasia.

SUMMARY

Trophic and vasomotor disturbances with dissociated sensory changes, usually of the lower and sometimes of the upper extremities, were found in most of the male and in a few of the female members of a family some of the members of which also had harelip and cleft palate. The trophic changes first became apparent as a perforating ulcer of the feet and began at about the same age. The syndrome seems best attributed to an organized dysgenesis of the central nervous system of the type described by Fuchs under the term myelodysplasia.

THE CLINICAL APPLICATION OF TESTOSTERONE

WALTER M. KEARNS, M.D.

MILWAUKEE

The milestones along the march of knowledge of the testicular hormone were marked in 1849 by Berthold's [1] injection of testicular tissue into capons, with production of the secondary male characteristic of comb growth; in 1889 by Brown-Séquard's [2] attempt at rejuvenating himself by injection of crude watery extracts of dog or guinea pig testes; in 1911 by Pezard's [3] intraperitoneal injection into capons of crushed hog testes, with the production of comb growth; in 1927 by McGee's [4] injection of alcoholic extract of the lipoid fraction of bull testes and its detection in a five day assay on capons; from 1930 to 1938 by the development of a method for the extraction of androgens from the urine with quantitative assay on

From the departments of urology and biochemistry, Marquette University School of Medicine.

Read before the annual meeting of the State Medical Society of Wisconsin, Sept. 15, 1938, at Milwaukee.

The testosterone propionate for this study (oretone and oretone ointment) was supplied by the Schering Corporation.

capons by Koch, Gallagher, Domm and Womack;[5] in 1931 by Butenandt's[6] extraction from the urine of androsterone in pure crystalline form; in 1935 by the preparation by Laqueur and his co-workers[7] of testosterone, the form in which the hormone occurs in the testes, and in 1935 by the observation by Laqueur and his co-workers[8] of the still unidentified substance, an acidic and fat-soluble substance which appears in the testes, the adrenals and the urine and has the property of greatly activating testosterone. The identification of the x substance may be an important step in the advancement of therapy with androgenic hormones.

During the past three years several investigators have isolated and prepared a large number of androgens. Koch[9] listed over thirty androgenic substances which had been described, all closely related and similar structurally to the estrogens and cholesterol.

Until two years ago the results in male hormonal substitution were unsatisfactory. It is true that some temporary relief had been recorded at San Quentin prison after Stanley's[10] injection of testicular mush into the musculature of the anterior abdominal wall,

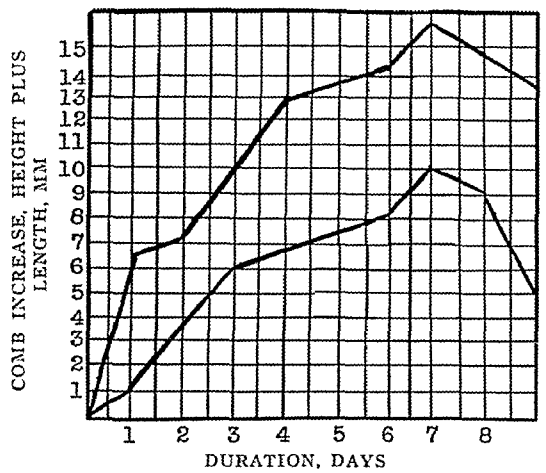

Chart 1.—The curves indicate the comb growth in two series of five capons which received injections of two different extractions of androgens from a six day specimen of urine from a normal student. The specimen was equally divided into two parts. With one part Koch's method was used, acid hydrolysis with a minimum of heat followed by benzene extraction in the new Koch apparatus (upper curve, 31.7 capon units a day). With the other half, extraction with dibutyl ether was employed (lower curve, 14.3 capon units a day). A comparison of the curves indicates the higher yield obtained with the benzene method.

but the procedure was never widely accepted. Nor was the isolation of testosterone from the bull's testicle of any great clinical help, since there is little storage of hormone in the tissue and only minute amounts are extractable. The yield is so small that it would require the rendering of 100 bull testicles for the daily maintenance of one castrate. Not until the recent commercial production of testosterone has an effective method been available.

Since the isolation and identification of testosterone and the perfection of a method of synthesis by degradation of sterols, the hormone has been placed on the market by several drug houses. Some esters of testosterone have been proved to be more potent and more prolonged in their effect than the free hormone. Testosterone propionate is the combination offered by the manufacturers.

The advent of these potent preparations has resulted in exaggerated claims and theories which expand beyond the limits of reasonable speculation. The medical literature is already being cluttered with premature reports demonstrating a lack of knowledge that may result in confusion on the part of the physician attempting to gain an understanding of a most complicated and profound problem. Koch's[9] thorough review of the subject of male hormones is a most exhaustive and enlightening treatise. It is well worth reading by all physicians.

MATERIALS AND METHODS

During the past ten months my associates and I have made an experimental study of testosterone and testosterone propionate. With the aid of Dr. Joseph Bock, professor of biochemistry at Marquette University Medical School, we have been able to make extractions of urine for androgenic activity for various types of patients, including castrates and patients with postpubertal cryptorchidism. Extractions and assays were made before and after treatment with testosterone administered by injection and by inunction. In recent extractions the ingenious method of Koch, in which benzene is used as the extracting agent, has been closely followed. In our hands benzene has proved to be the best solvent and the Koch still a most efficient method (charts 1 and 2). Assays have been made by injections into capons or by the application of an alcoholic extract to the capon's comb and recorded in terms of international capon units. More recently assays have been made by the colorimetric method described by the Callows and Emmens[11] and by Oesting.[12] The Oesting colorimeter has been adopted.

INDICATIONS

Caution in the choice of patients must be exercised, as the possibility of overstimulation and glandular imbalance must be kept in mind. Testosterone must not be injected indiscriminately into every knave who aspires to emulate the sex behavior of the cock or the squirrel. Because of the possibility of the later atrophy of the testicles, long periods of treatment of adolescent boys and young men must be avoided unless clinical evidence of hypogonadism and low urinary output of the androgens has been demonstrated.

CASTRATES

Six castrates were recalled from my past practice and that of two other urologists, Dr. Warren Leaper and Dr. James King. These patients had previously made the rounds of several physicians and received the usual

futile ministrations with orally administered and injected preparations, ending in despair. They were broken men—nervous, apprehensive, depressed, unable to concentrate and devoid of libido, with pale sallow thin wrinkled skin—bearing their crosses tenaciously but at best barely able to hold part time positions. True to form, these patients had had definite shrinkage in the size of their prostate glands, in some instances to such a degree that the gland was indiscernible by digital rectal examination.

Basal metabolism tests, tests for blood cholesterol, Aschheim-Zondek tests with assay of the urine for gonadotropic substance and sugar tolerance tests were repeated periodically. Originally these patients deviated in varying degrees from the normal, with a lowered basal metabolic rate, increased dextrose tolerance and a lowered blood cholesterol content. The Aschheim-Zondek test has not been positive in a single instance. A sufficient number of recent tests to indicate any decisive changes have not yet been completed.

The most sensitive clinical indicators of testicular function are the seminal vesicles and the prostate gland. Carl R. Moore,[13] Callow and Deanesly[14] and McCullagh[15] have called attention to the prompt atrophy of the prostate after castration. Experimentally, in castrated male animals the administration of androgenic agents elicits a prompt response in the increase in size of the atrophic prostate and seminal vesicles.

The injection of testosterone propionate produced a change in the patients as definite and pleasing as anything in my experience. Ten mg. administered twice weekly has completely rehabilitated them. With two, injections of 5 mg. twice weekly were sufficient. Increased strength and endurance, a desire to expand their work, the appearance of libido, erections, ejaculations, ability to copulate and an increase in the growth of the beard have all been observed in their return to normality. After from three to six weeks the prostate gland regenerates perceptibly, and it approaches the normal size in from six to eight months. One very religious patient, working as an orderly in a local hospital, threatened to discontinue treatment because of the appearance of annoying erections, and he would have deserted had it not been for the concomitant appearance of well-being and ability to work without extreme exhaustion. Foss[16] reported that a castrate while receiving 140 mg. of testosterone in a week acquired priapism which was unrelieved by intercourse but abated several days after the dose had been diminished.

TESTOSTERONE IN OINTMENT

About six months ago, on the suggestion of Dr. Carl R. Moore[17] of the University of Chicago, testosterone as an inunction was employed with castrates. Moore[18] has more recently reported on the potency of androgenic substance applied to the skin of animals.

Three of the castrated patients and two patients with cryptorchidism who were given testosterone ointment (each centimeter containing 2 mg. of free testosterone) have reported excellent results, at least equal to the effect obtained with injections. With the application of 2 cc. each day the dose applied to the skin was somewhat more than the injected amount. The total average weekly dose administered to the castrates was 20 mg. by injection and 28 mg. by inunction. Patients are directed to rub the ointment vigorously for twenty minutes into a hairless area of skin, preferably on the anterior abdominal wall. The application is made each day at bedtime.

Corroborating the good clinical outcome, proof of the absorption of the substance by the human skin was obtained through the demonstration of increased androgenic activity in the urine (chart 3).

The potency of many drugs administered through the skin by inunction is well known to the physician. Through the ages the treatment of syphilis rested mainly on the mercurial inunction because of its proved

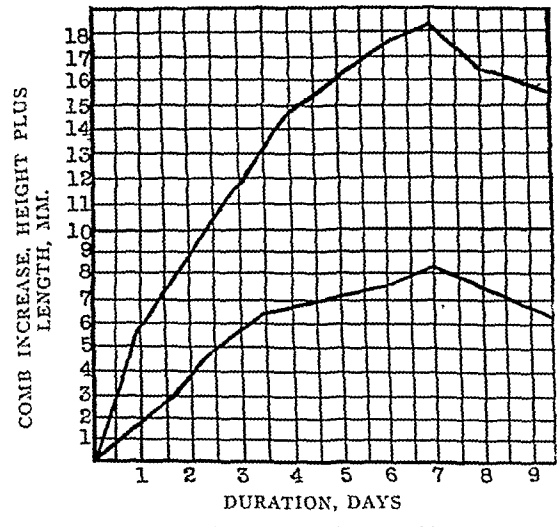

Chart 2.—These curves of comb growth in capons illustrate the markedly diminished excretion of androgens in an elderly patient with melancholia and prostatic hypertrophy (lower curve, 5.3 capon units a day) as compared with the excretion of a normal student (upper curve, 37.3 capon units a day). In each case the extraction was performed on a five day specimen of urine. Testosterone propionate injected in 25 mg. doses markedly alleviated the mental symptoms in the patient.

prompt and prolonged therapeutic action. As evidence of absorption of the mercurial through the intact skin, toxic gingival, intestinal and renal manifestations frequently developed when proper reserve was not exercised in its administration.

Macht[19] has recently reported the result of a long and careful study on the absorption of drugs and poisons through the skin and mucous membranes. He commented on the sound rationale underlying many of the older therapeutic procedures employing inunction, pointing out the benefits and dangers as well.

The problem in substitution therapy with testosterone is to arrange the administration so as to imitate the steady continuous activity of the normal glands and avoid alternation of deficiency and wasteful excess of the hormone. In an ointment the hormone is slowly and continuously available to the body. It is possible that this method of administration of androgens may have wide-

spread acceptance. At any rate, for patients who have difficulty in reaching the physician it offers an effective form of treatment.

POSTPUBERAL CRYPTORCHIDISM

Two patients with postpuberal cryptorchidism, 23 and 32 years of age, have been treated. In both there was retarded development of the secondary male characteristics associated with atrophy of the testicles. Each patient had the appearance of a boy of 16 years, with small face, slender build, high pitched voice and no hair on the face or in the axillae, with typical eunuchoid bodily form, with full hips and girdle distribution of fat, and with arm span greater than body height. The patient of 32 had a small amount of pubic hair. The penis was less than 2 inches in length and of very small caliber. After one year of treatment with antuitrin-S no change was observed. The patient married during this course of treatment and his efforts at intercourse were unsatisfactory. Eight months ago treatment with testosterone propionate was instituted in injections of 25 mg. twice weekly. The penis enlarged remarkably and in six months had more than doubled its size. Intercourse with well defined orgasm is now being carried out three times weekly in a gratifying manner. The

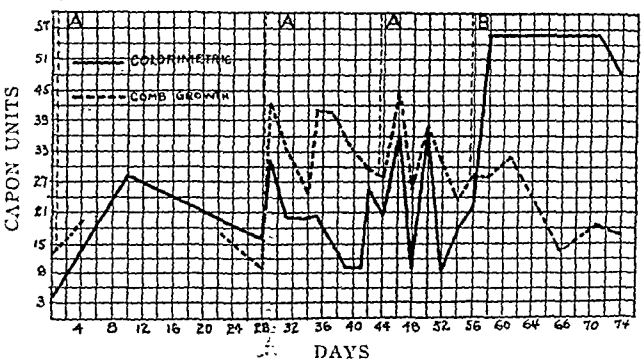

Chart 3.—A comparison of the results obtained in assaying, in duplicate, twenty-three urinary extractions, part of each extract by the colorimetric method and another part of each extract by capon comb growth response after topical application. *A* indicates 50 mg. of testosterone and *B* testosterone ointment. The extractions were made on twenty-four hour urinary specimens from a eunuchoid collected at intervals during a seventy-four day period. The broken line charts the results in terms of average comb factor increase following five daily applications of alcohol solution of extract to the comb of two capons. Each extraction of the androgenic substance was made up to 20 cc. in 70 per cent alcohol, and 3 cc. of this was applied daily for five days, a total of 1.5 cc., or 7.5 per cent of the total extraction, applied to each capon comb. The average percentage increase of comb factor (factor = the square root of the length multiplied by the height of the comb in millimeters) was recorded except on the tenth day, when the containing vial was broken. The solid line charts the results on the same extracts obtained by colorimetric assays translated into international capon units. Note the parallelism between the colorimetric assay and the comb growth response beginning on the first day before treatment was started and the continuance of the parallelism through the period when several intramuscular injections of 50 mg. each of testosterone crystals were made. With the institution on the fifty-fourth day of inunction treatment (8 mg. of testosterone a day) a wide deviation occurred, with apparently the presence of substance in the urinary extracts producing a much greater change in the colorimetric readings than in the capon comb response. The decrease in the output of androgens during the last three days of observation, recorded in both methods of assay, was caused by the omission of treatment every other day.

other patient, 23 years of age, has experienced a similar good result. In both patients the prostate gland has grown appreciably and axillary hair and a small amount of hair on the upper lip have appeared. The experience of Riches [20] and more recently that of Vest and Howard [21] demonstate the need of larger maintenance doses for this type of patients, approximately double the dose used for castrates. Kenyon administered 25 mg. of testosterone propionate intramuscularly from five to seven times weekly for from twenty-eight to ninety-five days to four eunuchoids.[22] Thereafter three of them received from 10 to 25 mg. from three to seven times weekly, with interruptions for 152, 108 and 160 days respectively. In all instances there were an early increase in the frequency of erections and a marked increase in the size of the prostate as early as the twelfth day. The penis elongated from 1 to 2 cm. in all but one case. Changes in the hair of the face, pubis and thighs and deepening of the voice occurred promptly with the large dose used. Moreover, Kenyon observed nitrogen and sodium retention and a slight increase in the body weight.

Twenty-five mg. twice weekly proved in our cases to be the minimal dose for maintenance of well-being and continuance of gradual improvement.

A larger dose of ointment is also required for eunuchoids. Four cc. of ointment (2 mg. per cubic centimeter) is applied daily. The total weekly dose reaches approximately 56 mg. of testosterone, which compares with the injected dose of 50 mg. a week. While the response to either method of administration occurs less promptly than in the castrate, the effect is no less definite. In fact the objective sign of penile growth offers a definite indicator of the effect. A reduction of dose results in a less satisfactory clinical course.

In this type of patient, as in the castrate, there is an unquestionable indication for endocrine therapy, because unmistakable deficiency is recognizable clinically and the reassuring response to treatment is readily observed. In these two groups the effect of testosterone may be truly called rejuvenation. The physician may now humanely corral and treat with testosterone these morbid semi-invalids with as much precision as he would use in treating with insulin patients with advanced diabetes. Testosterone may not contain all the components of testicular secretion, but it does control dramatically some processes associated with its deficiency.

SUMMARY

1. In castrated patients and in those with hypogonadism due to cryptorchidism the administration of testosterone brings about an effective substitution.

2. Beneficial results have been obtained through the intramuscular injection of testosterone propionate and equally good results through the inunction method with free testosterone in a greaseless base.

Men of First-Rate Ability.—There are questions which concern the elucidation of disease and its processes in man which are among the hardest that human intelligence and endeavor have to answer. Clinical Science especially requires, for the solution of its many and varied problems, men of first-rate ability. To the younger generation the opportunities now offering, the security that is assured, are of a kind undreamt of a few years ago. The days are passing when a worker was inevitably forced away from the work of his choice to find his livelihood in practice. The time is approaching very nearly to us when it will be impossible for men spending long years in the successful solution of problems in Clinical Science to fail to draw around them at least a few eager young workers from their own teaching institutions, when it will be impossible for them to remain isolated intellectually, and surrounded only by students preoccupied by more directly practical pursuits and interests.—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

EFFECT OF VITAMIN K ON THE CLOTTING TIME OF THE PROTHROMBIN AND THE BLOOD

WITH SPECIAL REFERENCE TO UNNATURAL BLEEDING OF THE NEWLY BORN

W. W. WADDELL JR., M.D.
AND
DUPONT GUERRY III, M.D.
CHARLOTTESVILLE, VA.

PART 1

The desirability of finding some agent which might materially lessen the incidence of cerebral accident and unnatural bleeding in the neonatal period prompted this study of the effect of vitamin K concentrate on the prothrombin-clotting time and the clotting time of the blood of the newly born. Before presenting our results it seems advisable to review briefly the history of vitamin K concentrate.

During work on sterol metabolism in the chick, Dam [1] in 1929 observed that diets deficient in certain respects gave rise to a disease which closely resembled scurvy. In this disease spontaneous bleeding occurred in the affected animals, clotting time was markedly prolonged and the plasma prothrombin was reduced to extremely low levels. Later he and his co-workers [2] suggested that this condition, which failed to respond to ascorbic acid administered either orally or subcutaneously, was a deficiency disease brought about by exclusion from the diet of a certain antihemorrhagic factor which he termed vitamin K. This substance was found to be fat soluble and to occur in the easily soluble nonsterol fraction of unsaponifiable matter. Hog liver fat and alfalfa proved to be excellent sources for the substance, which in solubility and heat resistance appeared to be somewhat akin to vitamin E. Marked differences between this vitamin, however, and other known vitamins were apparent. These workers [3] also reported methods of concentrating and assaying this new antihemorrhagic factor.

Somewhat later, but independently, Almquist and his associates [4] described the same hemorrhagic disease in the chick and, in addition, developed a method of concentrating the antihemorrhagic factor contained in alfalfa meal. A quick method of assay was then reported by them,[5] and shortly thereafter a clear, colorless, crystalline substance containing one or more benzene rings and having a potency eight times that of the fraction remaining in the solution was isolated.

Clinical trial of extracts rich in so-called vitamin K naturally followed closely in the wake of experimental work. Hawkins and Brinkhaus [6] in their work on the cause of bleeding in dogs with bile fistulas found the plasma prothrombin markedly decreased in these animals and expressed the belief that the low prothrombin level was responsible for the hemorrhagic propensity. They found that the feeding of bile, with a sufficient diet, would increase the plasma prothrombin and that afterward the bleeding ceased.

Butt, Snell and Osterberg [7] of the Mayo Clinic reported striking results in the use of vitamin K and bile in the treatment of the hemorrhagic diathesis in cases of obstructive jaundice. Dam and Glavind [8] also reported favorable results in such cases but predicted that purpura and hemophilia, as well as other allied conditions in which the plasma prothrombin content is not lowered, would not respond to such therapy, a suggestion which has since been borne out.

The modus operandi of vitamin K in increasing the plasma prothrombin has not yet been elucidated. It is assumed that the product is absorbed by the intestinal tract in the presence of bile (it being fat soluble), but nothing is yet known concerning its metabolism after assimilation. The fact that bile is necessary for its absorption, however, accounts for the inability of a patient stricken with obstructive jaundice to absorb the vitamin; hence the low prothrombin content of the plasma. Both Dam and Almquist have observed that vitamin K can be produced by bacterial action in the intestine, and this appears to be the explanation for the failure of certain animals to acquire hemorrhagic disease though fed on a diet deficient in vitamin K.

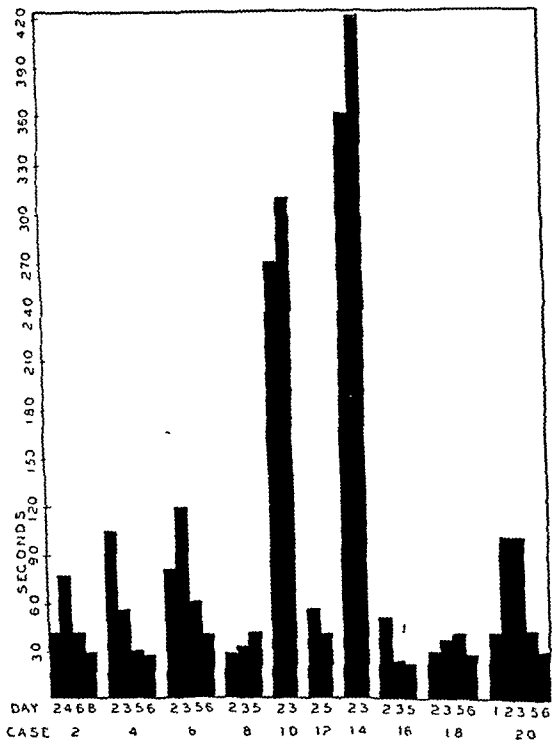

Chart 1.—Prothrombin clotting times for the control infants.

In this work we employed the method devised by Quick and his co-workers [9] for determining the prothrombin-clotting time. This method has been used by Snell, Butt and Osterberg [10] of the Mayo Clinic in their work on the hemorrhagic diathesis in jaundice, and it is their belief that, while it is a relatively simple procedure, it is accurate within practical limits and, as the originators contend, a very good index of the prothrombin level, since this time varies inversely with the prothrombin content of the blood.

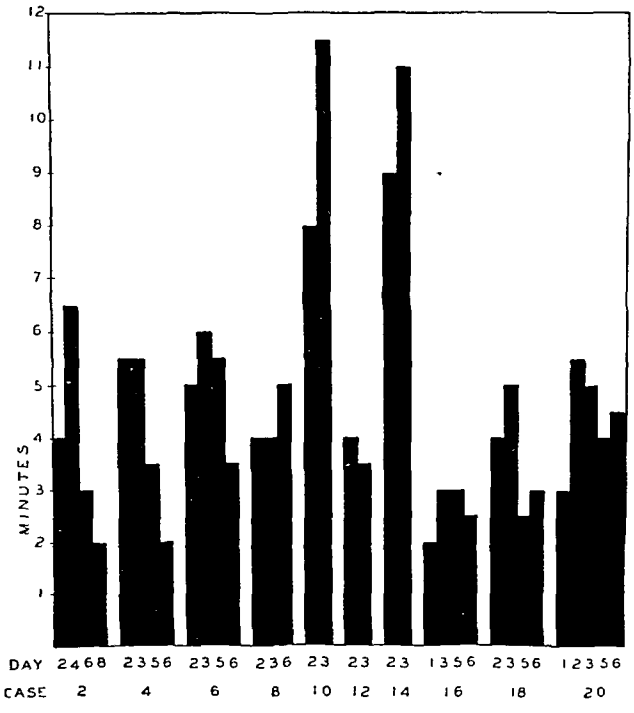

Chart 2.—Blood clotting times for the control infants

Brinkhaus, Smith and Warner [11] have found the prothrombin level of the newly born to vary considerably in different infants and in the same infant at different ages. These workers have further shown that for normal newly born infants the prothrombin values vary from 14 to 39 per cent of the level found for normal adults, while in a case of hemorrhagic disease the prothrombin level was extremely low, in fact less than 5 per cent of the adult norm.

With this work in mind it seemed logical to believe that vitamin K, which so materially affects the prothrombin level in jaundiced patients, might conceivably be effective in raising the prothrombin content of the newly born infant's blood and thereby prevent both spontaneous hemorrhage or that initiated by the trauma of labor. It is but a step further to postulate, should this be effective, that birth trauma may be minimized by administering this substance to the mother either before or shortly after labor has set in.

Twenty newly born infants served as subjects for the first part of this investigation. For ten control infants the prothrombin-clotting time and the clotting time of the blood were determined at varying intervals during the first week of life. To ten other infants vitamin K concentrate [12] was administered orally, at the end of twenty-four hours 1 cc., at the end of forty-eight hours 0.5 cc. and at the end of seventy-two hours 0.5 cc. The clotting times of the blood and the prothrombin were determined at intervals identical with those of the controls, the capillary tube method being used.

In all cases the prothrombin-clotting time was determined according to the method of Quick, blood specimens being obtained from the anterior longitudinal sinus. All such determinations were done by Dr. O. R. Kelly of the department of clinical laboratories of the University of Virginia Hospital.

Because of the meager knowledge concerning the prothrombin content of the blood of the newly born and the even more meager knowledge concerning the prothrombin-clotting time, it was necessary to establish our own controls. Although we had only ten, we obtained significant information from them. Chart 1 shows the prothrombin-clotting rate at various intervals in the first week of life for the ten control infants.

It seems obvious (1) that the blood of newly born infants differs markedly as regards the prothrombin-clotting time, unusually high rates being common, (2) that the blood of individual infants varies markedly on different days of life as regards the prothrombin-clotting time, (3) that the blood of certain infants is peculiarly deficient in prothrombin as determined by the prothrombin-clotting rate and that the period of most marked deficiency is between the ages of 48 hours and 72 hours and (4) that after the fifth day the rate tends to fall to an apparently common level. The last fact strongly suggests a relationship between hemorrhagic disease of the newly born and the prothrombin content of the blood, in that hemorrhagic disease rarely occurs after the fifth day of life, the time at which the prothrombin-clotting rate of the control infants appeared to approach a common level.

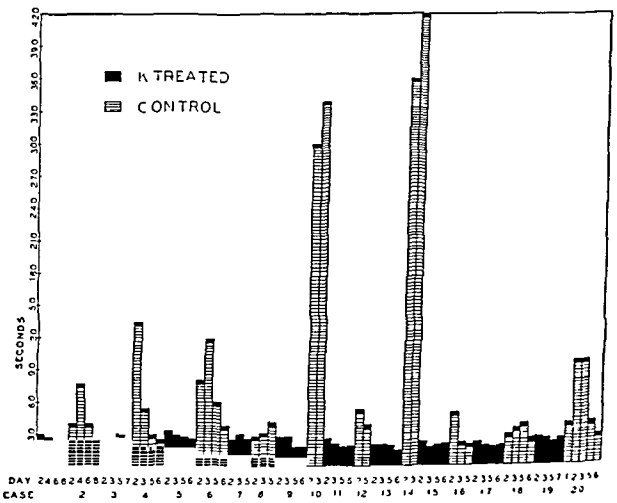

Chart 3.—Prothrombin clotting times for the control and treated infants

Chart 2 shows the blood-clotting time at various intervals in the first week of life for the ten control infants. All time intervals conform with those employed in the determinations of the prothrombin-clotting times. It seemed obvious (1) that the blood

10 Butt, H. R.; Snell, A. M., and Osterberg, A. E.: Further Observations on the Use of Vitamin K in the Prevention and Control of the Hemorrhagic Diathesis in Cases of Jaundice, Proc. Staff Meet., Mayo Clin. 13: 753-764 (Nov. 30) 1938; footnote 7.

11 Brinkhaus, K. M.; Smith, H. P., and Warner, E. D.: Plasma Prothrombin Level in Normal Infancy and in Hemorrhagic Disease of the Newborn, Am. J. M. Sc. 193: 475 (April) 1937.

12 The vitamin K concentrate used in this study was furnished by the Abbott Laboratories and is now available for general use.

of newly born infants differs markedly as regards the clotting time, (2) that the blood of individual infants varies markedly on different days of life as regards the clotting time, (3) that the highest clotting times occur at from 48 hours to 72 hours, (4) that no high clotting times are encountered after the sixth day of life and (5) that as the prothrombin-clotting time rises or falls so does the blood-clotting time rise or fall. This fact may well explain the high clotting time of the blood in hemorrhagic disease of the newly born.

In chart 3 the prothrombin-clotting times for ten control infants are staggered with the prothrombin-clotting times for ten infants treated with vitamin K. It is a significant and striking fact that no unusually high rates were observed for the latter infants and no unusual daily variation. In fact the highest rate encountered for these infants was 40 seconds. Apparently vitamin K concentrate will markedly lower the prothrombin-clotting time in the first few days of life and maintain it at a safe and surprisingly common level.

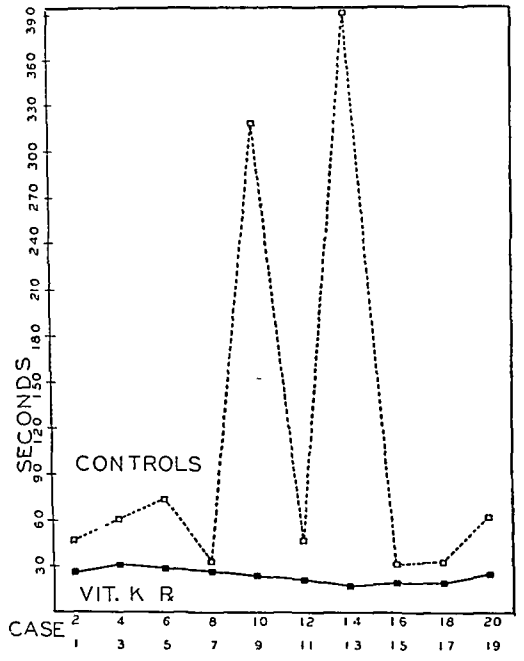

Chart 4.—Average prothrombin-clotting times for the control and treated infants.

In chart 4 the mean prothrombin-clotting times of the ten control infants are plotted in the form of a curve and a similar curve is plotted for the ten infants treated with vitamin K. The low level for the treated infants and the very even curve are most apparent.

We do not know what should be considered a safe prothrombin level. Butt, Snell and Osterberg in their report concerning the use of vitamin K in the preparation of certain patients with jaundice for operation said that a prothrombin-clotting time of more than thirty seconds was an indication for vitamin K therapy and a ten second fall in the rate evidence of a decided effect of vitamin K. The dramatic effect of this vitamin possible in the newly born would seem to be but the expression of a real need for prothrombin occurring at this age. It is not difficult to see why some of the control infants might have bled when subjected to the trauma of labor and delivery, and it is not difficult to see why spontaneous hemorrhage occurs at this age. On the other hand, it seems unlikely that spontaneous hemorrhage will occur in any infant receiving vitamin K and having prothrombin-clotting rates such as those recorded here.

In chart 5 the clotting times of the blood for the ten control infants are staggered with the clotting times of the blood for the ten infants treated with vitamin K. The generally lower level of the clotting time of the treated infants is apparent, with none of the daily variations so noticeable for the controls.

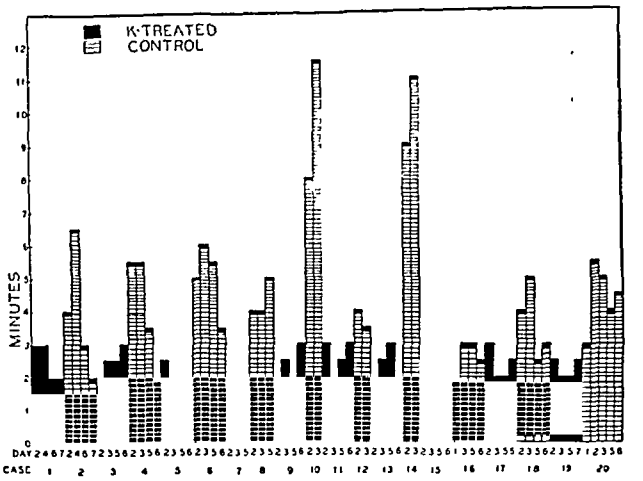

Chart 5.—Blood-clotting times for the control and treated infants.

The mean blood-clotting times of the ten controls and of the infants treated with vitamin K are expressed in curves in chart 6. The generally lower clotting time and its strikingly common level for the treated infants is very evident. Apparently vitamin K concentrate will consistently lower the clotting time of the blood in the first few days of life and maintain it at a common lower level. It is hard to visualize spontaneous hemorrhage

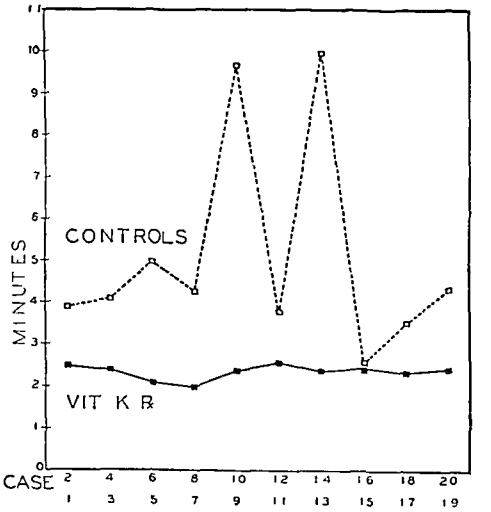

Chart 6.—Average blood-clotting times for the control and treated infants.

in the treated infants, with clotting times markedly lower than the supposed clotting time of the normal newly born infant.

The rapidity with which vitamin K concentrate reduces the prothrombin-clotting time and the blood-clotting time in a suitable case is remarkable, as shown in the following history:

CASE 1.—T., a baby girl, was born in the University of Virginia Hospital Feb. 12, 1939, of a syphilitic mother who had

received suitable treatment. At the time of the baby's birth, the mother's Wassermann reaction was negative. The infant appeared normal in every respect and the weight was 2,770 Gm. On the afternoon of February 15, the third day of life, the prothrombin-clotting time was found to be five and one half minutes and the coagulation time eight minutes. Two cc. of a concentrate rich in so-called vitamin K was administered by mouth. Two hours later the prothrombin-clotting time had dropped to forty seconds and the coagulation time from eight minutes to five minutes. Throughout the hospital stay the prothrombin-clotting time and the blood-clotting time remained consistently low, and on the seventh day the former was twenty-four seconds and the latter three minutes (chart 7).

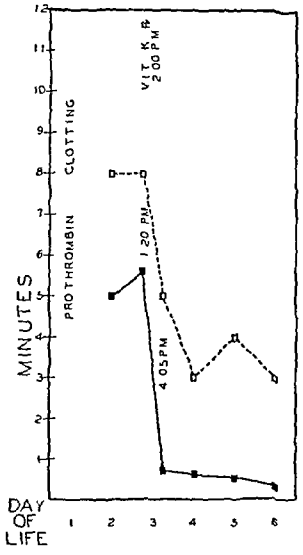

Chart 7.—Clinical data in case 1.

COMMENT

The whole subject of unnatural bleeding at the time of birth and in the first week of life is in a very confused state. No satisfactory classification of hemorrhage occurring at this time is available. This confusion has largely to do with what is or is not hemorrhagic disease of the newly born, at best only a clinical syndrome rather than a disease entity.

Because of its frequency and disastrous consequences, intracranial hemorrhage originating at the time of labor and delivery causes the greatest concern. We have always felt that trauma played only a secondary role in normal labor and delivery and that certain infants possess an inherent tendency to bleed under the stimulus of moderate trauma. Unusually high prothrombin-clotting and blood-clotting times may well account for such unnatural bleeding tendencies. Certainly symptoms and signs of intracranial hemorrhage frequently are not observed until many hours after delivery, and this suggests slow hemorrhage from a small bleeding point. The presumptive and factual evidence presented in this report suggests that vitamin K concentrate if administered immediately after birth may serve to check such bleeding and render harmless a slow oozing hemorrhage, which otherwise might well cause death or permanent mental and physical crippling.

In the prevention and treatment of spontaneous hemorrhage, concealed or apparent, associated with a high prothrombin-clotting and blood-clotting time and appearing within the first week of life, vitamin K concentrate should prove effective. The following case is presented as further factual evidence that vitamin K concentrate will check unnatural bleeding associated with a prolonged prothrombin-clotting and blood-clotting time.

CASE 2.—D., a baby girl born Feb. 12, 1939, in the University of Virginia Hospital, weighed 3,345 Gm. and appeared normal in every respect. On the second day after birth at 3:30 p. m. blood was removed from the longitudinal sinus. The prothrombin-clotting time was found to be six minutes. Blood from a puncture wound of the heel showed a clotting time of nine minutes. Slow oozing from this wound lasted for twelve hours. At 9:30 the following morning puncture of the fontanel was again done, and the prothrombin-clotting time was found to be seven minutes and the blood-clotting time eleven minutes. Two cc. of a concentrate rich in so-called vitamin K was administered by mouth. One and one half hours later the prothrombin-clotting time had dropped from six minutes to fifty-five seconds and the blood-clotting time from eleven minutes to four minutes. Oozing from the puncture wound of the heel ceased promptly after administration of vitamin K. Throughout the hospital stay the prothrombin-clotting time and the blood-clotting time remained consistently low, and on the seventh day the former was twenty-three seconds and the latter three minutes (chart 8).

We are unable to suggest what may be the effect of vitamin K on hemorrhage not associated with a high prothrombin-clotting time and blood-clotting time. It seems unlikely that any beneficial effects will result, since the disturbance in such cases appears not to be a matter of the clotting of blood but rather a change in the walls of small blood vessels which renders them permeable so far as their contents are concerned. In our experience cases of this nature are rare.

There would seem to be important surgical significance in the facts presented in this report. In view of the high prothrombin-clotting and blood-clotting times so commonly encountered in newly born infants, it would seem wise to administer vitamin K before any contemplated surgical operation at this age period. This simple precaution should greatly lessen the chance of unpleasant and serious bleeding at the time of and after operation. Even the simple operation of circumcision has at times been associated with serious and even fatal hemorrhage.

Believing as we do that trauma plays only a secondary role in many of the cases of intracranial hemorrhage associated with apparently easy and normal labor, we are engaged in a study to determine whether or not vitamin K administered to the mother before and after the onset of labor will materially affect the prothrombin-clotting time and the blood-clotting time in the newly born infant. The results obtained so far in this uncompleted investigation are most encouraging and will be published in the near future. If the prothrombin-clotting time and the blood-clotting time of the infant can be lowered by administration of vitamin K to the mother, the therapeutic application suggests vast possibilities. If the desired effects cannot be obtained through the mother by oral administration, it seems not unlikely that a preparation of vitamin K suitable for intravenous use will be available. At least one study is under way which has for its object the production of a suspension or colloidal solution for intravenous use.

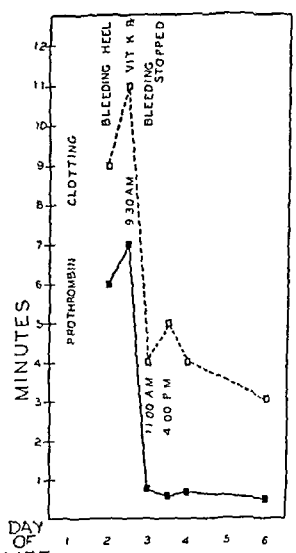

Chart 8.—Clinical data in case 2.

It is hardly necessary to stress the necessity of finding some means whereby the incidence of intracranial hemorrhage occurring at the time of birth may be materially lessened. Concerning this important subject we quote from Grulee and Bonar.[13]

13. In Brenneman, Joseph: Practice of Pediatrics, Hagerstown, Md., W. F. Pryor Company, Inc., vol. 1, chapter 42, p. 59.

We see, therefore, that of the deaths of the newborn, between 25 and 40 per cent may be attributed to intracranial hemorrhage, and that the number of cases of intracranial hemorrhage in maternity hospitals varies with the hospital but that it is probably as frequent as 1 to 25 or as low as 1 to 150 deliveries. If we were to estimate the number of deaths in the population at large from any one disease, or type of injury, we would be appalled to find that it occurred as frequently as 1 to 150 individuals.

This statement does not take into account the large army of mental and physical cripples who were so unfortunate as not to die as a result of their cerebral accident. A relatively short trial in any large lying-in hospital should prove or disprove the suggested therapeutic value of vitamin K concentrate and its possible effect on the present unhappy picture.

I REPARTITION OF POTASSIUM IN CELLS AND PLASMA

Dulière[1] reported in 1931 a constant enrichment in the serum potassium of blood kept in contact with cells over a period of days.

The manifestations of potassium poisoning have been well known since Blake's[2] observation in 1840. The symptoms in both cold[3] and warm[4] blooded animals have been reported. Such poisoning is not peculiar to the animal kingdom, for alterations in the concentration of potash in certain plant cells or in the mediums in which they live profoundly affect many of their normal reactions.[5]

Because of this, an investigation of the loss of potassium from cells and its increase in the plasma, as one of the abnormalities of stored blood, was felt necessary. An investigation seemed doubly imperative on account of the recent rapid rise of "blood banks," together with the growing conviction that blood kept too long is dangerous, as judged by an occasional severe reaction, a greater incidence of post-transfusion jaundice and an occasional unexplained death.

Normally human red cells contain twenty times as much potassium as there is in the plasma. It is the chief mineral base of cells. Naturally factors altering this distribution would make available an ever increasing amount of potassium in the serum of preserved blood.

FIRST SERIES

The first group of experiments was designed to check Dulière's statement. Two samples of the same human venous blood were collected with aseptic precautions and kept in pyrex flasks stoppered with cotton, in the dark, in a refrigerator at 4 C. in the following manner:

EXPERIMENT 1.—The blood, 250 cc., was kept under liquid petrolatum.

EXPERIMENT 2.—The blood, 250 cc., was mixed with 2.5 per cent solution of sodium citrate in sufficient quantity to make a mixture containing 0.31 Gm. per hundred cubic centimeters of blood.

At the same time a 5 cc. sample was mixed with heparin (Connaught) in a centrifuge tube and spun for one hour. This served as the sample for base line determinations.

Portions of the serum or plasma were pipetted off at twenty-four hour intervals for five days and then at approximately weekly intervals for a month. With each analysis, material for culture was taken and streaked on blood agar plates. These were observed for growth at the end of twenty-four and forty-eight hours.

Potassium determinations were done by the argenti-cobaltinitrite modification[6] of the method of Kramer and Tisdall,[7] the final colorimetric readings being made on the Evelyn photoelectric colorimeter.[8] The value given is the mean of two aliquots. Cell volume was determined by Sanford-Magath tubes spun for one hour at 2,000 revolutions per minute.[9] Specific gravity was measured by the method of Barbour and Hamilton.[10] The plasma protein content was calculated by the formula of Weech, Reeves and Goettsch.[11]

The following experiment is typical of the series as to method and results:

Dr. Drew is a Fellow in Surgery, Rockefeller Foundation

This study was made possible by a grant from the Blood Transfusion Betterment Association

From the Department of Surgical Pathology of Columbia University College of Physicians and Surgeons

Data presented at the Eleventh Annual Graduate Fortnight, the New York Academy of Medicine, Oct. 24-Nov. 4, 1938

EXPERIMENT 1.—*Blood kept under oil without a preservative.* The blood of the donor, Dr. J. S., was of group B.

Procedure.—In addition to the determinations, which served to provide basic values, made at the time of the bleeding, eight other sets of analyses were made, and the results were expressed in four ways (table 1):

1. Column 4; actually observed; serum potassium as milligrams per hundred cubic centimeters of serum.

2. Column 5; by calculation as milligrams of potassium in the serum of 100 cc. of blood. This figure for practical purposes gives at a glance the actual amount of serum potassium in every hundred cubic centimeters of blood on any given day when preserved in the stated manner.

3. Column 6; by calculation as milligrams of potassium given off into the serum by each hundred cubic centimeters of cells. This figure is theoretically more convenient for comparative purposes, as it obviates the differences created by bloods whose cell volumes may vary markedly from normal.

4. Column 7; as percentage of potassium which has diffused out of the cells.

Each day's values represent the sum of the increments to that particular day, care being taken throughout to estimate the amount of potassium removed in the various test samples. At each sampling a note was made concerning the presence and degree of hemolysis.

TABLE 1 (experiment 1).—*Blood Kept Under Oil Without Preservative*

1	2	3	4	5	6	7	8
			Milligrams of Potassium				
			Observed Value per 100 Cc. of Serum*	Sum of Increments		Percentage of Cell Potassium Diffused Out	Hemolysis (Observed)
				Per 100 Cc. of Blood	From 100 Cc. of Cells		
Date	Sample	Days					
3/27/38	1	1	40.0	8.7	16.0	4.5	0
3/28/38	2	2	68.6	21.1	39.2	11.0	0

4/15/38	7	20	206.4	78.6	145.2	40.9	++++
4/29/38	8	34	225.0	86.0	158.0	44.8	++++

* Values uncorrected for sample removed.

Values.—

Basic Values: hematocrit reading, 54.3 per cent cells and 45.7 per cent serum; plasma potassium, 21 mg., whole blood potassium, 202 mg. and cell potassium (calculated), 354 mg., per hundred cubic centimeters; specific gravity of plasma, 1.0274, and plasma proteins, 6.87 Gm. per hundred cubic centimeters.

Calculation:

(*a*) For base line or zero values: blood sample, 250 cc.; serum volume, 250×0.457 (percentage of serum) $= 114.4$ cc.; determined serum potassium, 21 mg. per hundred cubic centimeters, and total potassium in original serum, 24 mg.

(*b*) For first day's increment: blood sample, 2 cc.; serum potassium (observed value), 40.0 mg. per hundred cubic centimeters; potassium in 2 cc. sample, 0.8 mg.; potassium in residual serum, $114.4 - 2 \times 0.4 = 45$ mg.; total potassium in serum after twenty-four hours, $45 + 0.8 = 45.8$ mg.; increase in total potassium in serum in twenty-four hours, $45.8 - 24$ (originally present) $= 21.8$ mg.; increase in serum potassium of 100 cc. of blood in first twenty-four hours, $21.8 \times \frac{100}{250 \text{ (cc.)}} = 8.7$ mg.; amount of potassium given off in first twenty-four hours by each hundred cubic centimeters of cells, $21.8 \times \frac{100}{250 \text{ (cc. of blood)} \times 0.543 \text{ (percentage of cells)}} = 16$ mg., and percentage of cell potassium diffused out into serum in first twenty-four hours, $\frac{16 \text{ (amount lost)}}{354 \text{ (original cell potassium)}} = 4.5$.

In a similar manner each day's results were determined and expressed as the sum of the increments.

Results.—These are shown in chart 1 and table 1.

In each of the two flasks there was a steady rise in the serum or plasma potassium. In the hematocrit tube, however, for the few days observed, the increment was less and suggested that either heparin was a markedly superior preservative or the slow diffusion was the result of some other factor.

In each instance there was discernible discoloration of the supernatant fluid by the fifth day and obvious gross hemolysis by the fourteenth.

The data in table 1 suggest that blood kept under oil at a constant temperature loses in the first week at least 25 per cent of its cell potassium, at the end of three weeks about 40 per cent and from that time on diminishing quantities. In more practical terms, such blood at the end of the first week contains in the serum of each hundred cubic centimeters of blood at least 50 mg. of potassium and any time after two weeks at least 75 mg., the amount gradually increasing.

SECOND SERIES

The second group of experiments was designed (1) to check the results of the first series, (2) to ascertain the effect of trauma (such as shaking) on the rate of loss of potassium from cells and (3) to see what effect the shape of the container had on the rate of diffusion. The blood of the donor, Dr. G. S., was of group O. Five hundred cc. of blood was collected and placed in three pyrex flasks.

EXPERIMENT 3.—The blood, 150 cc., was kept under oil without an anticoagulant.

EXPERIMENT 4.—The blood was placed in a Sanford-Magath hematocrit tube containing heparin and spun for an hour.

EXPERIMENT 5.—The blood, 150 cc., was mixed with 50 mg. of heparin.

EXPERIMENTS 6 and 6B.—The blood, 200 cc., was mixed with the usual sodium citrate solution.

These flasks were treated in a manner similar to the first set. The results are shown in table 2.

From the observed values, none of the anticoagulants prevented the loss of potassium from the cells. The rate of diffusion appeared a little slower in the citrated blood. There was a distinct difference in the heparinized bloods (chart 2), that in the container with the larger interface showing the more rapid diffusion. This indicates that the shape of the container and not the anticoagulant was probably the cause of the slow diffusion in the heparinized blood in the first series. Here again, agitation by vigorous shaking hastened the process of diffusion (chart 3).

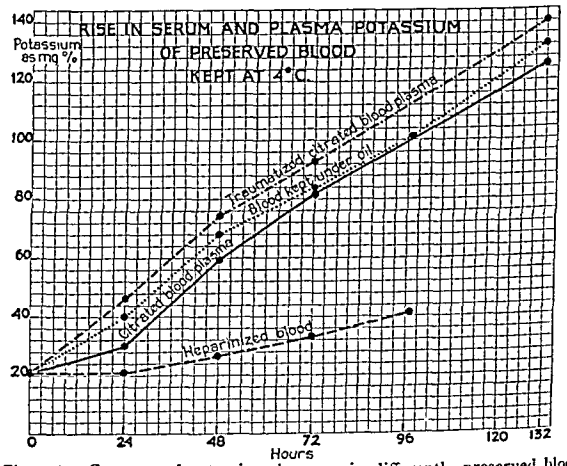

Chart 1.—Contrast of potassium increase in differently preserved bloods. Both the citrated blood and the blood stored under oil were in Erlenmeyer flasks. The heparinized blood was kept in a centrifuge tube. Data from experiment 1, table 1.

THIRD SERIES

In the third series four samples of fresh venous whole blood were preserved in 2.5 per cent solution of sodium citrate, 3 per cent solution of sodium citrate, Peyton Rous solution [12] and the Russian citrate solution.[13]

EXPERIMENT 7.—*Blood preserved in 2.5 per cent solution of sodium citrate.* The blood, from a professional donor, G. W., was of group O. To 125 cc. was added 17.5 cc. of 2.5 per cent solution of sodium citrate to give a mixture containing 0.31 Gm. per hundred cubic centimeters of blood. Each day a 2 cc.

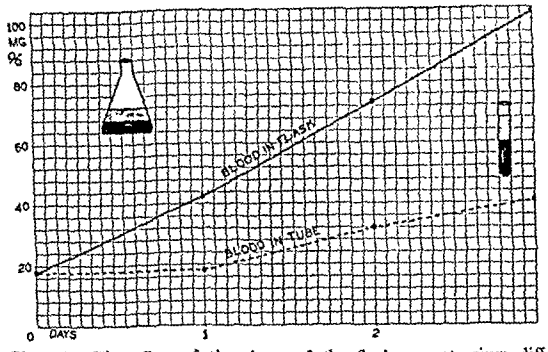

Chart 2.—The effect of the shape of the flask on potassium diffusion. Data from experiments 4 and 5, table 2.

sample was removed from the supernatant fluid without disturbing the cells and the potassium content determined as in experiment 1.

The results are tabulated in table 3 and graphically represented in charts 4 and 5.

EXPERIMENT 8.—*Blood preserved in 3 per cent solution of sodium citrate.* The donor was the same as in experiment 7 and the procedure was the same except that 15 cc. of a 3 per cent solution of sodium citrate in sterile water was used as the preservative for 125 cc. of blood. The gram percentages are exactly the same, 0.31.

The results are tabulated in table 4 and graphically represented in chart 5.

EXPERIMENT 9.—*Blood preserved in Russian citrate compound.* The blood of the donor, Dr. C. R. D., was of group O. Fifty cc. was added to an equal quantity of preservative made up according to the following formula: sodium chloride 7 Gm., sodium citrate 5 Gm., potassium chloride 0.2 Gm., magnesium sulfate 0.004 Gm. and distilled water 1,000 cc. The rate of diffusion was determined as in experiments 7 and 8.

The results are tabulated in table 5 and graphically represented in chart 5.

EXPERIMENT 10.—*Blood preserved in Peyton Rous compound.* The blood of the donor, Dr. J. S., was of group B. To 150 cc. was added 250 cc. of 5.4 per cent solution of dextrose in distilled water and 100 cc. of 3.8 per cent solution of sodium citrate. The high percentage of sodium citrate in this preservative contraindicates its use for transfusions; the cells, however, may be resuspended in saline solution and used. The results are shown in table 6 and chart 5.

SUMMARY, PART I

1. There is a daily increase in the amount of potassium present in the serum or plasma of whole blood kept in vitro under aseptic bacteriostatic conditions.

2. The transference of potassium from cells to plasma begins at the time of withdrawal from the blood stream. The rate is rapid at first and gradually diminishes.

3. The total amount found in the serum at the end of ten days reaches 25 per cent of the total potassium content of the red blood cells in the fresh state and at the end of thirty days may exceed 50 per cent.

4. The rate at which the potassium is given up by the cells is greatly increased by shaking.

5. The rate of potassium diffusion is evidently influenced by the shape of the container. The larger the interface area, the more rapid the diffusion (chart 2).

6. Hemolysis appeared at varying times in the different samples; none was present in the sample preserved in the Peyton Rous compound.

7. Changes observed in these experiments were not due to bacterial infection.

8. Sodium citrate in a mixture containing 0.31 Gm. per hundred cubic centimeters of blood is more effective as a preservative than the more complex Russian citrate compound.

9. The citrate-dextrose mixture of Peyton Rous prevents loss of hemoglobin from the cells but not loss of potassium.

II. A COMPARISON OF THE RATES AT WHICH CELLS LOSE POTASSIUM AND HEMOGLOBIN

In the third series of experiments, repeated attempts to measure accurately the small amounts of hemoglobin in the plasma of only slightly hemolyzed bloods were unsuccessful with the usual acid hematin methods such as those of Helige and Sahli. With the Pulfrich photometer, however, small daily increments were demonstrable with greater consistency. The method used is a modification of that described by Heilmeyer.[14] The content of hemoglobin may be calculated in grams per hundred cubic centimeters of plasma and then reexpressed as grams lost from the cells per hundred cubic centimeters of blood.

The potassium determinations were done as described in part I, the cultures on blood agar plates and the

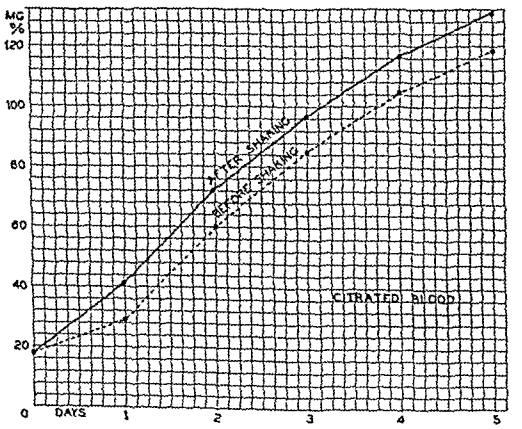

Chart 3.—Effect of shaking on preserved blood. Data from experiments 6 and 6B, table 2.

p_H determinations first by titration and then checked by means of a Helige glass electrode potentiometer which had been calibrated by buffers.

EXPERIMENT 11.—*Blood preserved in diluted Russian citrate compound.* The blood of the professional donor, J. F., was of group O.

Equal parts of blood and diluted preservative were mixed by adding 125 cc. of blood to 125 cc. of preservative which con-

14. Heilmeyer, Ludwig: Medizinische Spektrophotometrie, Jena, Gustav Fischer, 1933, p. 86.

tained 875 mg. of sodium chloride, 625 mg. of sodium citrate, 25 mg. of potassium chloride and 0.5 mg. of magnesium sulfate.[13]

The blood and the preservative were checked for initial p_H values, which were compared with the p_H of the mixture at the end of the experiment.

Hemoglobin determinations were done at the first suggestion of hemolysis. Cultures were taken at well spaced intervals.

The zero value used in determining the daily increments of hemoglobin was 40 mg. in the plasma from 100 cc. of blood. This quantity is our normal value for blood which has been centrifuged for one hour.

The basic values were as follows: hematocrit reading, 45.6 per cent cells and 54.4 per cent plasma; plasma potassium, 17.6 mg., whole blood potassium, 192.0 mg. and cell potassium (calculated), 400.0 mg. per hundred cubic centimeters; specific gravity of plasma, 1.0253; plasma proteins, 6.25 Gm. per hundred cubic centimeters; p_H of blood, 7.3 and p_H of preservative, 7.4

The results are tabulated in table 7.

EXPERIMENT 12.—*Blood preserved in sodium citrate and adrenal cortex extract.* The blood of the professional donor, J. F., was of group O. To 125 cc. was added 15 cc. of a 3 per cent solution of sodium citrate and 10 cc. of adrenal cortex extract, the mixture being treated like that of experiment 11.

EXPERIMENT 13.—*Blood preserved in undiluted Russian citrate compound.* The blood of the professional donor, J. F., was of group O. The procedure was similar to that of experiment 11 except that only one half the quantity of preservative was used and no distilled water was added. The 12.5 cc. of preservative contained 312.5 mg. of sodium citrate, to make a mixture containing 0.228 Gm. per hundred cubic centimeters of blood. The results are shown in table 9.

EXPERIMENT 14.—*Blood preserved in Grey's buffered solution.* The blood of the professional donor, J. F., was of group O. The procedure was the same as that in experiment 11 except that 112.5 cc. of blood was used and 12.5 cc. of preservative prepared according to Grey.[15] The results are shown in table 10.

Table 11 shows at a glance the difference in rates of hemolysis in the four types of preservative. The increases of each are expressed in grams in the plasma of 100 cc. of blood and then as percentage of hemoglobin lost from the cells.

Table 12 expresses the percentage loss of potassium from cells.

The information gained shows that none of the preservatives prevented an increase in plasma potassium,

and of the preservatives analyzed sodium citrate functioned best. The blood kept under oil manifested the same changes. The reason underlying the mechanism of potassium loss is obscure; the finding of an increase in ammonia may prove significant.

Amberson[16] has shown that hemoglobin itself is not toxic to the vertebrate body if it has been freed from stromas, and if the solution was properly balanced infusions containing from 12 to 14 per cent caused no abnormal reaction. The quantities present in the plasma of the most hemolyzed bloods under our observation have not approached this figure.

TABLE 12.—*Percentage Loss of Potassium from Cells; Comparison of Different Preservatives*

Days	2.5% Solution of Sodium Citrate	3% Solution of Sodium Citrate	Russian Citrate Compound	Peyton Rous Compound	Diluted Russian Citrate Compound	Solution of Sodium Citrate and Adrenal Cortex Extract	Undiluted Russian Citrate Compound	Grey's Buffered Solution
7	18.7	18.8	23.1	19.0	30.5	20.4	26.2	28.1
14	32.8	28.7	40.9	37.2	44.3	34.1	38.2	42.3

30	48.7	44.7	66.0	53.4	74.2	62.3	58.1	61 2

These potassium levels were confirmed in the laboratory of Dr. Robert F. Loeb on samples submitted Oct. 4, 1938.

SUMMARY, PART II

1. The erythrocytes of preserved blood lose potassium at different rates, depending in part on the type of preservative. This loss begins before the diffusion of hemoglobin. Hence the degree of hemolysis cannot be used as an index of potassium loss.

2. A high degree of potassium diffusion may be present in the complete absence of hemolysis (table 7).

III. THE TOXICITY OF POTASSIUM

With the observed increase of potassium in the plasma of stored blood, a reinvestigation of the toxic action of this base was deemed necessary.

16. Amberson, W. R.: Blood Substitutes, Biol. Rev., Cambridge Philosophical Soc. 12: 48-86, 1937.

The literature on the subject is abundant,[17] and some of the lethal doses are tabulated in tables 13 and 14.

Six years after Blake's[2] discovery that injections of potassium caused cardiac arrest in dogs, Bouchardat and Stuart-Cooper[18] in a series of fifty experiments established the lethal doses for fish, frogs, fowl, dogs and rabbits. Although this work was done in 1846,

TABLE 13.—*Lethal Doses of Potassium (Gustav Bunge, 1871)*

Animal	Weight Kg	Dose, Gm.	Salt	Time of Death	Authority
1. Introduced into Stomach					
Rabbits		3	KCl	30 min.	Guttmann
		1 6 4	KCl	40 70 min.	Bunge
Dogs	6	10 20	KCl	1 hr.	Podkopaew

		1-1 5	KCl	Immediate	Grandeau
		0 1	KCl	Immediate	Bunge
		0 0 1	KCl		Podkopaew
4. Intra Arterial Injection					
Dogs		1.5	KCl		Podkopaew

the conclusions are valid today, namely that the toxic action of potassium depends on the mode of administration, the rate of injection, the amount of potassium in the salt used and the individual resistance of the animal.

Concerning the toxicologic effects of potassium there are many contradictory data, owing in part to the choice of the animal. There is, however, fairly uniform agreement that small doses of potassium increase, while large doses weaken and paralyze, the normal functions of the nervous, glandular and muscular systems.

TABLE 14.—*Lethal Intravenous Doses of Potassium (Since Bunge)*

Year	Authority	Animal	Salt	Mg. of Potassium per Kg
1881	Feltz and Ritter	Dog	KCl	48
1883	Bochefontaine	Dog	KCl	100
1892	Dogiel	Dog	KNO_3	20
1906	Bouchard and Oliver	Dog	KCl	39 90
1910	Joseph and Meltzer	Dog	KCl	38 3
1938	Marenzi	Dog	KCl	20

Most authorities attribute death to cardiac paralysis: Claude Bernard,[19] Traube,[20] Grandeau,[21] Aubert and Dehn,[22] Bohm,[23] Dogiel,[24] Feltz and Ritter,[25] Bochefontaine,[26] Binet,[27] Hald,[28] Mathison,[29] Howell,[30] Gross[31] and Wiggers.[32]

Electrocardiograms taken in the course of conditions associated with hyperpotassemia[33] or after ingestion,[34] injection,[35] perfusion[36] or topical application[32] of potassium salts show a variety of changes. These range from slowing of the rhythm, decrease in PR interval and low voltage, to bundle branch block, ventricular fibrillation and cardiac arrest.

The respiratory and cardiac centers are other focal points of potassium action. Hooker[37] had demonstrated, by infusing the medulla of dogs, that an increasing concentration of potassium over calcium in the spinal fluid is followed by both respiratory and cardiac arrest.

Vascular smooth muscle is constricted by an increase in potassium concentration.[38] Of importance is the recent experimental work of Katz and Linder,[39] who reported coronary dilatation with small doses and complete occlusion with larger doses of potassium. In this condition, sodium salts caused relaxation of the constricted vessels.

The effect of potassium on blood pressure depends on the manner of injection and amount of the salt injected.[40] In general a decline in blood pressure occurs with intravenous[41] and a rise with intra-arterial medication.[42]

Aubert and Dehn,[22] however, reported a rise with very small intravenous doses. Mathison[29] has confirmed both the pressor and depressor effects of potassium salts.

Toxic oral doses are promptly vomited, and with certain animals ligation of the esophagus[43] was necessary to demonstrate that absorption from the gastro-

intestinal tract may be toxic. The lethal doses, however, are from seventy to a hundred times the intravenous ones.

ANIMAL EXPERIMENTS

To test again the toxic action of potassium, the rabbit and dog were selected. The former has a high and the latter a low potassium content of the blood cells.

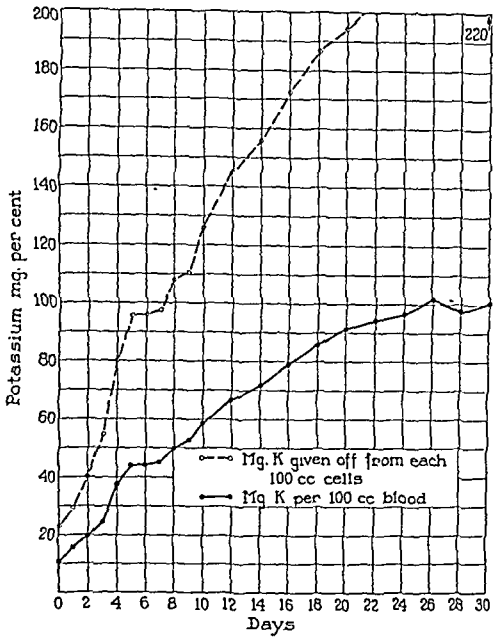

Chart 4.—Preservative: 70 cc. of a 2.5 per cent solution of sodium citrate for each 500 cc. of blood. The diffusion of potassium is expressed in two ways: (*a*) the amount given off from 100 cc. of cells (theoretical) and (*b*) the increase in the potassium in each hundred cubic centimeters of blood. Data from experiment 7, table 3. The points for this chart were obtained by adding the initial base line values to the daily increments expressed in the table. This chart shows the actual amount of potassium in each hundred cubic centimeters of blood. In giving a transfusion of 1,000 cc. of this blood on the thirtieth day one would be giving 1 Gm. of potassium. Under such circumstances extreme caution would need to be exercised, for example in the rate of injection.

TABLE 15.—*Rabbits Given Injections of Solution of Potassium Chloride*

Rabbit	Weight, Kg.	Concentration of Solution as Gm. per 100 Cc.	Amount Injected as Cc.	Place and Speed of Injection	Potassium Chloride as Gm.	Potassium as Mg. per Kg.	Results
1	2.01	0.381	550	Peritoneum Slowly	2.1	547	Died on seventh day
2	2.0	0.381	500	Peritoneum Slowly	1.96	514	Revived and given another injection on twelfth day
3	2.5	0.381	40	Jugular vein Rapidly	0.152	32	Convulsion; died at once
4	2.36	0.381	40	Jugular vein Rapidly	0.152	34	Convulsion; died at once
5	2.0	0.381	50	Jugular vein Rapidly	0.19	49	Convulsion; died in few minutes
2	2.0	1.16	42	Jugular vein Slowly	0.487	128	Convulsion; died in 15 min. 5 sec.

In our first set of experiments five rabbits were used. In three the potassium chloride solution was injected rapidly into the jugular vein, with immediate death after a generalized convulsion. In two the solution was injected into the peritoneum; one lived a week and the other recovered and was given an intravenous injection on the twelfth day. The results are given in table 15.

In the second group of experiments four dogs were used in an attempt to determine more accurately what part the speed of injection plays in the production of toxic symptoms. A typical protocol is presented in table 16. The actual lethal dose was given when 275 cc. (138.5 mg. of potassium per kilogram) of fluid had run in. The additional 25 cc. was accidental and may account for the excessive rise shown by the last value for plasma potassium. The gradual fall in the specific gravity and protein content of the plasma may be considered as an indication of blood dilution. The changes in the cell volume as recorded by hematocrit readings are more difficult to explain. The initial fall represents dilution and the secondary rise a sudden transport of fluid from the blood.

A summary of the experiments on dogs is presented in table 17.

TOXICITY IN MAN

The literature is very meager regarding the toxic action of potassium on man. Orfila [43] in 1818 reported the following cases:

A man with periodic fever took 1½ ounces (45 cc.) of potassium nitrate, thinking it was epsom salt, and died in ten hours.

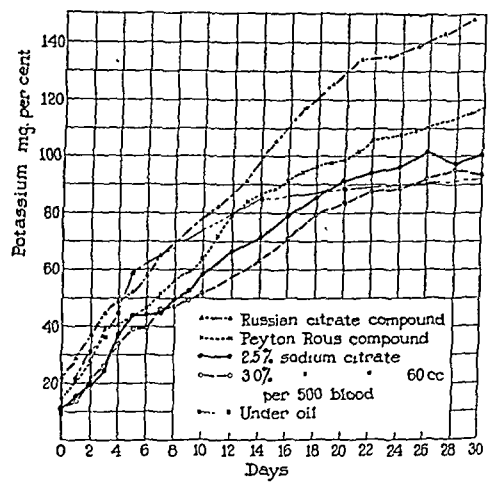

Chart 5.—Comparison of increase in plasma potassium in differently preserved bloods. The actual amounts of potassium in the plasma of 100 cc. of blood on any given day are shown. The points were obtained as in chart 4. The data are from experiments 1, 7, 8, 9 and 10, tables 1, 3, 4, 5 and 6.

A woman aged 40, suffering from heartburn, took 3 or 4 drachms (11 to 15 Gm.) of potassium sulfide in 4 ounces (120 cc.) of water by mistake. Severe vomiting ensued, followed by unconsciousness, the presence of black blood in the capillary system, especially of the lips and eyelids, and paralysis of the left side of the body. The action of the heart was barely perceptible and then failed. Autopsy showed the mouth and esophagus to be clean; the gastric mucosa was not greatly involved, except that here and there it was dry and red, with sulfur precipitates.

Many other cases were reported; when death was rapid the picture was one of shock and when it was delayed one of severe gastro-enteritis.

Bunge [43] observed that small doses do not affect the pulse or temperature.

Kylin [44] in 1925 injected from 0.15 to 0.8 Gm. of potassium chloride intravenously and reported a fall in the blood sugar content.

44. Kylin, E., and Engel, A.: Ueber die Einwirkung der K-ionen auf den Blutzuckerspiegel, Klin. Wchnschr. 4: 653, 1925.

Arden [45] in 1934 recorded a case in which 15 Gm. of a potassium salt was taken by mouth. Muscular weakness, paresthesia of the hands and feet and a metallic taste in the mouth appeared in forty minutes and lasted from three to four hours.

Electrocardiographic tracings after the ingestion of potassium salts equivalent to 4.3 Gm. of potassium element have been reported.[31]

5. Recovery may be effected by artificial respiration, cardiac massage, the use of oxygen, injections of salt solution [46] and administration of cortical extract in large doses.[35]

COMMENT

The employment of preserved blood has increased during the past twenty years because of its numerous advantages.[47]

TABLE 16.—*Infusion into Dog of Isotonic (1.16 Gm. per Hundred Cubic Centimeters) Solution of Potassium Chloride*

Time	Elapsed Time in Minutes	Infusion	Hematocrit Reading, Percentage of Cells	Specific Gravity of Plasma	Plasma Proteins, Gm. per 100 Cc.	Whole Blood Potassium as Mg. per 100 Cc.	Plasma Potassium as Mg. per 100 Cc.	Source of Blood	Comment
10:25 a. m.		Before anesthesia	49.0	1.0262	6.56	24.5	22.7	Leg vein	Blood for base line slightly hemolyzed; given 30 mg. per Kg. of pentobarbital sodium
10:35 a. m.	0	After anesthesia; infusion started	44.6	1.0248	6.09	20.1	14.0	Leg vein	
10:44 a. m.	9	After 100 cc.	38.9	1.0240	5.81	24.2	20.2	Jugular vein	*Rate of infusion 20 drops a minute after first 30 cc.*
11:29 a. m.	54	After 200 cc.	40.2	1.0237	5.72	36.8	40.1	Jugular vein	Cyanotic, with irregular paired respirations, during a period when fluid went in too fast
11:39 a. m.	64	After 275 cc.	47.4	1.0231	5.52	49.2	62.1	Jugular vein	Convulsion, stopped breathing, sphincters relaxed; heart fibrillating
11:41 a. m.	66	After 300 cc.*	38.6	1.0195	4.28	67.0	172.0	Right side of heart	Heart stopped; blood clear; no hemolysis

At death Potassium in cerebrospinal fluid from basal cistern, 51.8 mg. per hundred cubic centimeters and in urine, 74.4 mg. per hundred cubic centimeters

Autopsy heart dilated, no pericardial effusion, bladder full; no petechial hemorrhages

* 25 cc. accidentally run in rapidly after convulsion

TABLE 17.—*Dogs Given Injections of Isotonic (1.16 Gm. per Hundred Cubic Centimeters) Solution of Potassium Chloride*

Dog	Weight, Kg.	Solution Injected as Cc.	Potassium Chloride Injected as Gm.	Potassium as Mg. per Kg. of Body Weight	Time, Minutes	Plasma Potassium Before Injection, Mg. per 100 Cc.	Plasma Potassium at Death, Mg. per 100 Cc.	Comment
1	9.8	100	1.16	62.1	3½	18.9	99.5	Pentobarbital sodium anesthesia, 30 mg. per Kg.; fluid run rapidly into vein by infusion; died after convulsion
2	10.3	120	1.392	73.0	18½	22.8	51.5	No anesthesia; fluid administered by syringe, 10 cc. at a time, slowly; died after a convulsion

						15.5	25.6	Spinal fluid
4	12.0	275	3.19	139.0	64	22.7	172.0	Pentobarbital sodium; fluid run in slowly by infusion; died after convulsion
							51.0	Spinal fluid

SUMMARY, PART III

1. The parenteral administration of potassium is associated with toxic manifestations of both muscular and nervous tissue together with a depression of the central nervous system.

2. The almost specific action of potassium is on the heart and circulation, with disturbances varying from diminished cardiac output to immediate diastolic arrest.

3. We have reaffirmed the lethal doses for animals previously reported.

4. The rate of injection is of particular importance, for when the potassium is given slowly several times the usual lethal dose is tolerated.

Of the many preservatives used, none tested prevented the diffusion of potassium from cells. In several hemolysis was slower and in one it did not take place at all, yet the diffusion of potassium was not altered. The remainder showed definite hemolysis; in some it started as early as the fifth day. All this illustrates the inadequacy of present methods of storage.

M. J. **1**: 691-695 (June 22) 1918

Although the observation that red blood cells lose potassium is not new,[48] no attempts have been made to prevent this loss. One of the problems of the future therefore is an attempt to keep blood under such conditions that both diffusion of the salts and hemolysis are prevented. The required knowledge may come through a better understanding of the laws which govern cell metabolism, diffusion and surface phenomena.

Naunyn[49] in 1868 first described the toxic properties of laked blood. His observations have been reaffirmed by many subsequent investigators, beginning with Landois,[50] but the nature of the toxic substance or substances has yet to be revealed.

Phemister[51] and Phemister and Handy[52] reported that there was something in slightly laked bloods which caused vasodilatation and in more severely traumatized blood which caused vasoconstriction. It was not histamine, not products of the disintegration of epinephrine and not the pituitary principle, nor did it develop as the result of changes in oxygen, carbon dioxide or hydrogen ion concentration, shifts in temperature or exposure to light or air. Petroff and his associates[53]

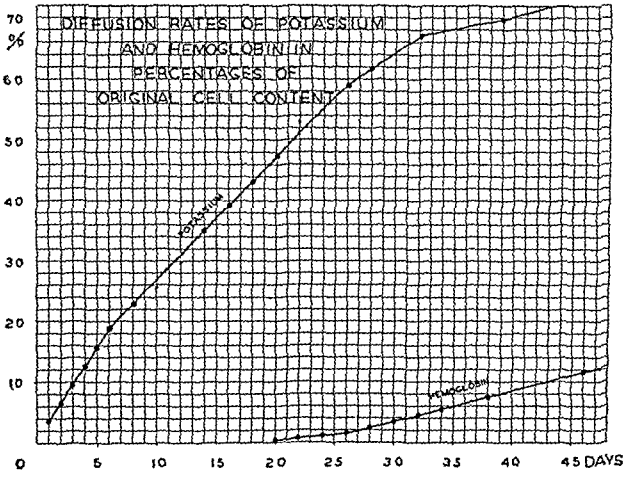

Chart 6.—Blood preserved in solution of sodium citrate and adrenal cortex extract. These curves illustrate that diffusion of potassium occurs before diffusion of hemoglobin and indicate the necessity of criteria other than hemolysis in assaying the various types of preservatives.

have observed such vasoconstriction of the splenic, renal and pulmonary vessels following the injection of hemolyzed blood but did not isolate the causative factors. Amberson[16] has established the fact that the toxic factor is not hemoglobin.

Kronecker[54] as long ago as 1882 suggested that the toxic effects of laked blood were due to its high potassium content. The finding of a large increase in the plasma potassium of preserved blood again raises this question. The intravenous lethal dose for man has not been observed. Studies on animals suggest that a rapid transfusion of from 3 to 5 liters of blood with a plasma content of 100 mg. per hundred cubic centimeters would be necessary to kill an adult. Blood preserved for thirty days by the methods now in use would contain potassium at this level, but it is unlikely that such quantities of stored blood would be used except as a slow continuous drip. It is probable, however, that such blood often may be used in quantities sufficient to cause toxic manifestations from its high potassium content.

The rapid administration of large quantities of blood preserved too long may be dangerous in conditions associated with hyperpotassemia, specifically in the dehydration of cholera,[55] intestinal obstruction,[56] intestinal fistula[57] and severe burns.[7]

Likewise its use seems contraindicated in both renal[58] and hepatic insufficiency[59] as well as in those diseases in which potassium retention is manifest, such as typhoid, influenza and pneumonia.[7]

In certain disorders of the ductless glands linked with disturbances in salt metabolism,[60] such as parathyroid tetany[61] and the collapse state of addisonian crises,[62] the giving of highly potassic blood may be dangerous.

On the other hand, in conditions of hypopotassemia, or potassium lack, preserved blood may find a specific use.

Finally, in hemorrhage and shock,[63] in which the need for blood is greatest and in which preserved blood finds its greatest usefulness, its improper use would seem to carry the greatest danger.

This study has been limited to potassium and hemoglobin. No claim is made that in potassium alone lies the noxiousness of preserved blood. Observations

regarding the relative toxicities of magnesium,[64] ammonia and phosphorus will be reported subsequently.

CONCLUSIONS

1. There is a daily increase in the plasma potassium of preserved blood kept under aseptic, bacteriostatic conditions, with increments reaching as high as 1,000 per cent.

2. None of the preservatives tested prevent this diffusion of potassium from the cells, the lowest rates being found in blood preserved in a mixture containing 0.3 Gm. of sodium citrate per hundred cubic centimeters.

3. Agitation, such as shaking, hastens the loss of potassium from the cells.

4. The shape of the container markedly influences the rate of potassium diffusion; the greater the interface area between the cells and the supernatant plasma, the greater the rate of diffusion. This suggests that tubular containers may be preferable to wide-bottomed flasks.

5. There is no parallel between the rates of diffusion of potassium and hemoglobin; hence the degree of hemolysis cannot serve as an index of plasma potassium.

7. In pathologic states associated with potassium retention or sensitivity, the use of blood preserved too long seems ill advised.

Clinical Notes, Suggestions and New Instruments

SULFANILAMIDE IN THE TREATMENT OF OTITIS MEDIA

GILBERT E. FISHER, M.D., BALTIMORE

The efficacy of sulfanilamide in the treatment of acute otitis media due to the beta hemolytic streptococcus has been tested on eighty-eight patients and the results controlled by a similar group who were not given sulfanilamide. In both of these groups a red, protruding tympanic membrane was incised early in the course of the disease or the opening in a spontaneously ruptured membrane of the drum was enlarged to secure adequate drainage. The only difference in the treatment was the administration of sulfanilamide. The accompanying table shows the monthly incidence of otitis media due to the beta hemolytic streptococcus throughout the year and the striking difference in the number of mastoid operations and other complications in the two groups. The effect of the drug on the duration of the discharge was striking; those given sulfanilamide recovered in one third the time.

To obviate the possible objection that the results in these two groups of patients are due to a seasonal difference in the virulence of the infecting organism, I have listed for each month the number of patients given sulfanilamide and those who did not receive sulfanilamide. They are about evenly divided. The table also shows that infections of the ear are most common in December, January, February and March, although in two of the four cases in which septicemia developed the infection began in June in one and in November in one.

The total number of patients observed was 183. Most of these were treated in the outpatient department and their home care was inadequate.

Of ninety-five patients who had a paracentesis but were not given sulfanilamide, sixty-six required a mastoid operation.

Of eighty-eight patients who had a paracentesis and were given sulfanilamide, only seven required a mastoid operation.

Of ninety-five patients who were not given sulfanilamide, four had septicemia; three of these recovered after operation and one died.

Of eighty-eight patients who were given sulfanilamide, none had complications.

The average duration of otorrhea of ninety-five patients who were not given sulfanilamide was sixty-five days.

The average duration of otorrhea of eighty-eight patients who were given sulfanilamide was twenty-three days.

The sulfanilamide, with an equal amount of sodium bicarbonate, was always given by mouth. Provided the patient is seen daily, I have found that a safe and effective dose is 10 grains (0.65 Gm.) three times a day for the first four days and 5 grains (0.3 Gm.) three times a day thereafter. If the patient is in the hospital and is watched closely for the first signs of toxicity, and if the severity of the infection warrants a larger amount of the drug, the dosage for both adults and children may be increased for a limited period up to 20 grains (1.3 Gm.) per kilogram of body weight. It is desirable to keep the concentration of sulfanilamide in the blood at a constant level, and for this reason frequent small doses are given rather than larger doses at longer intervals. The drug is rapidly excreted through the kidneys, and the best results are obtained by limiting the intake of fluids.

There are certain toxic symptoms that should be looked for by the nurses and physicians. All patients receiving sulfanilamide in adequate doses are cyanotic, but this is not a sign of toxicity. The undesirable effects of the drug are:

1. Increasing weakness and lassitude: If the general condition warrants it, the dose should be reduced or the drug discontinued for a few days.

2. Loss of appetite: The same consideration should be given as for 1.

3. Nausea and vomiting: Sulfanilamide should be discontinued and intravenous dextrose and saline solution given.

4. Fever, which decreases when the drug is withdrawn and increases when it is begun again: If the patient's general condition is good and local conditions in the wound do not explain a continued low grade septic temperature, discontinuance of the drug may be tried for a few days.

5. A progressive fall in hemoglobin: Transfusions should be begun and the dosage reduced or the drug discontinued.

6. Dermatitis, especially the exfoliative type: Sulfanilamide should be discontinued.

7. Severe hemolytic anemia with jaundice: Sulfanilamide should be discontinued and a transfusion given.

8. Agranulocytosis: Sulfanilamide should be discontinued and a transfusion given.

Monthly Incidence of Otitis Media Due to the Beta Hemolytic Streptococcus

	Beta Hemolytic Streptococcus Otitis Usual Treatment, No Sulfanilamide			Beta Hemolytic Streptococcus Otitis Usual Treatment Plus Sulfanilamide		
	Monthly Distribution of Cases	Number of Cases Requiring Mastoidectomy	Complications	Monthly Distribution of Cases	Number of Cases Requiring Mastoidectomy	Complications
January	19	16	0	21	2	0
February	16	14	2*	19	1	0
March	13	9	0	15	1	0
April	7	5	0	8	1	0
May	8	5	0	7	0	0
June	5	2	1*	4	1	0
July	4	1	0	1	0	0
August	0	0	0	0	0	0
September	1	0	0	1	0	0
October	6	3	0	0	0	0
November	2	0	1*	1	0	0
December	14	11	0	11	1	0
	95	66	4	88	7	0

* Positive blood culture.

The appearance of any one of these eight symptoms is a warning that the patient does not tolerate the drug well, and the decision as to whether the dose should be reduced or the drug discontinued depends on the seriousness of the infection and the general condition of the patient. Reduction of the dose or discontinuance of the drug should be considered when one or more of the first four symptoms appear, but it is imperative to discontinue giving sulfanilamide when any of the last four symptoms make their appearance.

HEMOCHROMATOSIS WITHOUT PIGMENTATION OF SKIN

RESISTANCE TO PROTAMINE ZINC INSULIN

HENRY J. JOHN, M.D., CLEVELAND

When one is confronted with a case of diabetes, enlarged liver, palpable spleen and ashy gray color of the skin the presumptive evidence is that one is dealing with a case of hemochromatosis. To prove this one can perform a biopsy of the skin, and if this shows the pigment the diagnosis is settled.

In the case I am reporting there were severe diabetes, an enlarged liver, a palpable spleen and an ashy gray color. A biopsy of the skin showed no pigmentation. Clinically the condition was hemochromatosis, but the lack of pigment in the skin raised a question. The patient was a man aged 42 who had diabetes of a year's standing. He had always been dark but more so in recent years. His brother was dark skinned but had no diabetes. His general health was always excellent until April 1937, when he began to lose weight, and at this point slight polydipsia and polyuria developed. A few weeks later the diabetes was discovered and he was treated unsuccessfully with a dietary regimen. From three to four months before admission he was put on insulin; the symptoms improved but loss of weight persisted. The loss of weight was from 275 to 185 pounds (125 to 84 Kg.) at the time I first saw him, Feb. 3, 1938, when the sugar content of his blood morning, noon and night was 309, 389 and 353 mg. per hundred cubic centimeters on 40, 0 and 30 units of protamine zinc insulin a day. He was a man of robust build, larged boned and somewhat under par. The blood pressure was 110 systolic and 80 diastolic. The temperature and pulse rate were normal. The skin was dark and scaly. There were tenderness over the right frontal sinus and a mucopurulent nasal discharge. The Wassermann reaction was negative. The icterus index was 10. The urea nitrogen content of the blood was 23.2 mg. and the cholesterol content 226 mg. per hundred cubic centimeters. The electrocardiogram showed a shifting pacemaker and occasional dropped beats, some slurring of QRS group and slight elevation of $S\text{-}T_1$, $S\text{-}T_2$ and $S\text{-}T_4$. X-ray examinations showed a bulge in the region of the left ventricle, with no general enlargement. The right frontal sinus was partly cloudy. Roentgenograms of the bones showed slight osteoporosis, with a small calcified lesion anterior to the cervical vertebrae. The chest was clear.

Diabetic status.

The diabetic status can be followed from the chart. The average sugar content of blood on 70 units of protamine zinc insulin at the start was around 350 mg. per hundred cubic centimeters, and the patient was losing nearly 200 Gm. of sugar in the urine. A change over to increasing doses of insulin reduced the average sugar level of the blood to about 200 mg. and the glycosuria to zero on the fourth day in the hospital. At this time the sinus infection was aggravated; roentgen treatment to the sinus was used, and during the infection the sugar content of the blood rose to its original level, although the urine's twenty-four hour excretion was on the average about 50 Gm. The insulin intake was raised to 140 units a day (four doses), and on this the sugar level of the blood dropped to an average of about 250 mg., and the glycosuria nearly subsided. It was at this point that I substituted protamine zinc insulin, an equivalent dose of two injections a day. The sugar content of the blood rose promptly, and excretion of sugar rose over 100 Gm. Again insulin was substituted, and on March 2 the patient had what was thought to be a cardiac infarct, and the sugar content on that day dropped to a low level of 69, 68 and 104 during the day. The insulin intake was reduced as low as 65 units and gradually raised to the former dose. The patient left the hospital on the afternoon of March 7 and died the next day of cardiac failure when he got up from bed against advice.

Here then was a man relatively insensitive to protamine zinc insulin. The impression was definitely that of hemochromatosis but biopsy of the skin failed to confirm it. It was left to autopsy to settle the question definitely.

At autopsy hemochromatosis of the liver, spleen, pancreas, kidney, heart, adrenal glands and portal, peripancreatic and periaortic lymph nodes was seen. There were marked atrophy and infiltration of the pancreas by fat, slight "bronzing" of the skin, splenomegaly (45 Gm.), ascites (1,500 cc.), hydrothorax (1,500 cc. on the right and 500 cc. on the left), edema of subcutaneous tissues, hypertrophy and dilatation of the heart (550 Gm.), fatty degeneration of the heart and mural thrombus of the apex of the left ventricle. A recent infarct was evident in the right kidney. There were passive hyperemia of the gastrointestinal tract, dilatation of the umbilical vein, moderate dilatation of the esophageal veins and acute fibrinous pleuritis and compression atelectasis of the right lower lobe.

Microscopic examination of the heart showed a large amount of pigment deposited principally at the nuclear poles, but in some fibers extending throughout the length of these; this proved to be hemosiderin. Stains for hemofuscin gave negative results. There were an enormous number of fat droplets within the muscle fibers; there was no evidence of infarction.

The pancreas too showed an enormous amount of fatty tissue, an increase in the connective tissue and a diffuse infiltration of pigment in this overgrown connective tissue. The islets of Langerhans were relatively large and well defined and contained an enormous number of granules of pigment. The epithelium of the acini was heavily laden with the pigment, as were the interstitial tissues.

The kidneys, liver, lymph nodes, lungs and spleen showed hemosiderin, which was absent in the other organs.

Hemochromatosis is comparatively rare. This is the first case which I have encountered among 4,941 cases of diabetes. Diabetes in these patients is secondary to hemochromatosis, which precedes and the pigment of which eventually incapacitates the insulogenic apparatus to diabetic status. The primary rise in the sugar level of the blood in these cases is likely due to the interference with the storage of glycogen in the liver, which is enlarged from fatty degeneration and the cells of which are filled with pigment. The cardiac action is interfered with from the same cause. It is easy to see how the individual cells of the cardiac muscle become incapacitated when the pigment practically crowds out the intracellular mass. Heart failure is bound to come if any additional strain is put on the heart, as was the case here. Practically all of the classic picture was present in this case: enlarged liver, enlarged spleen, ascites, abdominal pain, diarrhea, vomiting, impotence, somnolence and apathy, low blood pressure, cardiac failure and diabetes. The only varying factor was the fact that no pigment could be demonstrated either in biopsy of the skin or at postmortem examination in the presence of the ashy gray color which was so typical. The other point in question was the

large dose of insulin needed for control and the relative insensitivity to protamine zinc insulin. The protamine zinc insulin was not used during the active stage of sinus infection, so that could not be explained on this basis, but about a week after the infection had subsided. It is possible that protamine zinc insulin may not be as effective as insulin in hemochromatosis, a point which will have to be determined by further observations.

THE PRESERVATION OF MUSCLE FUNCTION IN BELL'S PALSY

PHILIP LEWIN, M.D., CHICAGO

The same orthopedic principles that apply to other lesions of the peripheral nerves should apply in Bell's palsy, namely, maintenance of muscular tone until return of nerve function, thereby keeping the muscle receptive to nerve impulses if, as and when they reappear.

Most textbooks on neurology offer descriptions of the etiology, pathology and diagnosis of the lesion but are strikingly inadequate with regard to treatment. My purpose here is to describe a method of splinting some of the facial muscles.

Adhesive plaster splints with string, producing overcorrection of deformity.

Bell's palsy may follow exposure to cold, as in sleeping in a drafty room or riding by an open window in a train or automobile. The onset is usually sudden, with pain behind the ear and in the neck. The palsy may be recognized when the patient awakens in the morning, at which time all or any one of the facial muscles may be affected. Fever may or may not be present.

In a typical advanced case the forehead cannot be wrinkled, the buccinator muscles cannot be contracted and whistling is impossible. The upper lid cannot be firmly closed and may be completely paralyzed. The nasolabial fold is obliterated. There is no apparent atrophy. The amount of facial paralysis varies in each case, and the reaction of degeneration determines this quantitatively.

Recovery occurs in a variable time. It may be hastened by physical therapy and by galvanism applied to the nerve and muscles. The upper facial fibers may get into the lower division and each wink of the eye may cause a twitch of the muscles about the mouth. The usual order of regeneration is the buccinator, the zygomatic and the superior levator muscle. Anastomosis with the hypoglossal or accessory nerves has been tried in cases in which there has been very little recovery, but with little success.

REPORT OF A CASE

A man aged 49 had facial palsy of the right side, apparently due to exposure to the wind and rain while riding in a motor car three days previously. He was seen by Dr. L. J. Pollock, who confirmed the diagnosis and prescribed court-plaster splinting. A search of the literature failed to reveal a pattern as a guide. One was therefore designed and made in the surgical dressing department of Michael Reese Hospital, a likeness of which is shown in the accompanying illustration. The splint is made of adhesive plaster with hooks such as gynecologists use in making abdominal binders for postoperative patients. After ten days of splinting the patient was given a series of galvanic treatments by Dr. Pollock five days apart. A complete recovery followed.

55 East Washington Street.

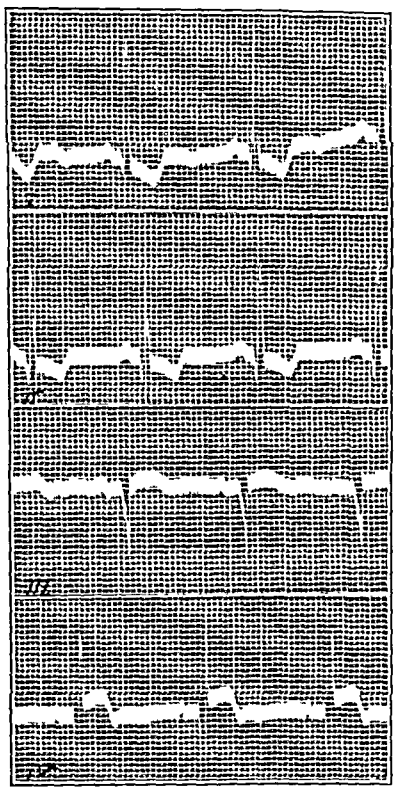
ANGINA PECTORIS AND SPASM OF THE CARDIA WITH PAIN OF ANGINAL DISTRIBUTION ON SWALLOWING

JOSEPH EDEIKEN, M.D., PHILADELPHIA

The similarity of the pain of angina pectoris and the pain due to certain lesions of the gastrointestinal tract is not unusual and is well known. Furthermore, the immediate cessation of an attack of angina pectoris following eructation of gas and, conversely, the initiation of an attack following a heavy meal or gaseous distention is not uncommon.

My purpose in this communication is to report a case of angina pectoris in which there was evidence of coronary and aortic disease and spasm of the cardia and in which attacks of pain similar in final distribution, but occasionally somewhat different in initial location, was produced by swallowing. Although the two types of pain were very similar in character and distribution, they differed in provocative causes and mode of relief.

B. D., a white woman aged 67, seen May 6, 1937, had suffered from chronic arthritis, hypertension and angina pectoris for a number of years, but the latter condition had been worse during the past few years. On effort or excitement a severe substernal pain would develop, radiating down both arms to the fingers and associated with a feeling of suffocation. Two weeks before this examination, following a severe emotional upset, similar attacks developed on swallowing, so that she had been afraid to eat solid food. The only point of difference between the attacks on effort and those on swallowing was that the latter sometimes started in the fingers and radiated upward to the chest. She experienced the same sense of suffocation as during the attacks on effort.



On physical examination the patient appeared quite ill. The pupillary reflexes were normal; the retinal vessels were sclerotic. There were several bad looking teeth. The chest was emphysematous and there were rales at both bases. The heart did not appear enlarged nor was the supracardiac area widened. There was a loud, rasping systolic murmur at the apex and base. The first sound at the apex was faint; the second aortic sound was accentuated. The blood pressure was 184 systolic, 76 diastolic. The peripheral vessels were sclerotic. The liver was not enlarged but there was slight pretibial edema.

The electrocardiogram presented here showed evidence of advanced myocardial disease and the orthodiagram showed the heart to be of normal size, but the apex was rounded, suggesting left ventricular hypertrophy. The region of the pulmonary artery was prominent and the left auricle was enlarged in the oblique and lateral views. The blood count showed 95 per cent hemoglobin, 4,950,000 red cells and 10,800 white cells, of which 72 per cent were polymorphonuclear leukocytes. The urine was normal except for a faint trace of albumin and an occasional hyaline cast. The blood sugar was 88 mg. per hundred cubic centimeters of blood, and the urea nitrogen 14 mg. The Wasserman reaction of the blood was negative.

Bed rest was advised and the patient placed on a prescription containing theophylline, phenobarbital and small doses of digitalis. She was also given an alkaline powder after meals and glyceryl trinitrate 1/100 grain (0.0006 Gm.) for the attack. One

From the Edward B. Robinette Foundation, Medical Clinic, Hospital of the University of Pennsylvania.

week later, May 14, she complained bitterly of attacks of pain on swallowing unrelieved by glyceryl trinitrate. These were so severe that she refused everything but liquids, which did not cause as severe pains as solids. She was therefore placed on extract of belladonna and extract of hyoscyamus, of each one-twelfth grain (0.005 Gm.) four times a day, in addition to the aforementioned drugs. Improvement was marked, and on June 11 she was entirely free of pains and was permitted out of bed. X-ray examination of the stomach and duodenum by Dr. Louis Edeiken July 7, seven weeks after treatment with antispasmodics, revealed that the esophagus was displaced posteriorly by an enlarged left auricle. The extreme lower end of the esophagus was narrow but its outline was regular. There was definite delay in the passage of the opaque mixture and a slight hesitancy in the passage of the opaque capsule at the lower end of the esophagus. The stomach showed that considerable air had been swallowed with the ingestion of the barium meal. The stomach was normal in size, shape and position, freely mobile, flexible and not tender; peristalsis was regular and active, and the stomach emptied itself within six hours. No deformities were observed. The bulb of the duodenum was regular in outline and normal. At the six hour examination the stomach was completely empty and the head of the barium column was in the terminal ileum; at the twenty-four hour examination the head of the column was in the rectum.

Electrocardiogram taken May 6, 1937. Chest lead taken with right arm electrode at apex and left arm electrode at angle of scapula. Elevation of ST interval in lead 4 may be due to digitalis.

Thereafter she was entirely free from attacks on swallowing but continued to have attacks on effort and excitement. These attacks were relieved by glyceryl trinitrate. September 11 she reported that attacks were few in number and only on effort. She was again seen October 4 after her return from the seashore. She had a few attacks on effort but attacks on swallowing had again developed. She admitted, however, that she had not taken medication for several weeks because she had been away from home. She was again placed on belladonna and hyoscyamus and November 20 reported attacks only on effort. She felt fairly well until April 10, 1938, when she began to have severe attacks of pain without any definite relationship to meals, effort or excitement. April 29 she reported that the attacks were almost continuous and she was again advised to go to bed. May 4 a coronary occlusion developed and she died May 9. Postmortem examination was not permitted.

This case is of interest because of the acute onset of pain on swallowing, complicating angina pectoris of long duration. The attacks of pain provoked by swallowing and effort were very similar in character and distribution and each was also accompanied by a sense of suffocation. Although the mechanism of the attack on swallowing appeared to be different than that on effort, the data on hand do not permit their differentiation with any degree of certainty. Electrocardiographic changes during the different attacks might have been helpful in proving the single or multiple origin of the various attacks, but unfortunately these were not obtainable. Two possible explanations for the attacks of pain following swallowing present themselves: (1) the pain was due to spasm of the cardia and (2) the attack was angina pectoris induced by the esophageal abnormality.

The association of cardiospasm with aneurysm, aortitis and angina pectoris has been noted by Verbrycke,[1] who reported twenty-three cases. In his series, cardiospasm was not accompanied by pain. The occurrence of dyspnea, cough, palpitation and anginal pain in cardiospasm, however, has been reported by Starling and Camps,[2] but in their cases the esophagus was markedly dilated and dilatation of the cardia was followed by relief of cardiac and respiratory symptoms. It is conceivable that a dilated esophagus, when distended by food, may exert considerable pressure on the mediastinal structures. X-ray examination in our case indicates that pressure was not responsible for the acute onset of pain on swallowing. Spasm of the cardia was noted, which in contrast to cardiospasm is considered by Friedenwald and Morrison[3] as a mild degree of obstruction in the lower end of the esophagus, temporary in character and unassociated with dilatation of the esophagus, a condition which frequently, as in our case, follows an emotional upset.

Esophageal pain similar in character and distribution to that of angina pectoris is stated to have been produced experimentally. The Jacksons[4] have concluded from their experiments on dogs that pain originating in the portion of the esophagus and adjacent mediastinum that lies between the horizontal midline of the heart and the upper opening of the thorax radiates down one or both arms. Morrison,[5] in his experiments on normal students, has shown that, regardless of the site of the local balloon distention in the esophagus, pain of anginal distribution can be produced by distention in the upper, middle or lower portion of the esophagus. Morrison states that temporary changes in the electrocardiogram follow balloon distention of the esophagus.

Our data do not warrant considering spasm of the cardia as the sole cause of pain on swallowing. The chief differences between the two types of attacks of pain were as follows: The attacks of long standing angina pectoris were induced by effort or excitement, relieved by rest and glyceryl trinitrate and uninfluenced by antispasmodics. The attacks that followed swallowing were not influenced by rest or glyceryl trinitrate but were relieved by antispasmodics. These observations suggest that spasm of the cardia was a significant factor in the mechanism responsible for the attacks of pain after swallowing. We have been unable to find a report of a similar case in the literature, although von Bergmann[6] has found by x-ray examination that dilatation of the esophagus at or just above the cardia is frequently found in patients with angina or "anginoid" symptoms.

SUMMARY

1. A woman had spasm of the cardia which complicated effort angina of several years' duration. Evidence of coronary disease, aortic disease and spasm of the cardia was demonstrated by electrocardiogram and x-ray examination.

2. Attacks of pain on swallowing were very similar in character and distribution to those of angina pectoris provoked by effort or excitement, except that sometimes the former started in the fingertips and radiated to the chest, whereas the latter always started in the chest.

3. Rest in bed was followed by relief of anginal attacks but did not influence the pain on swallowing until antispasmodics were given; conversely, antispasmodics relieved the pain on swallowing but attacks on effort or excitement persisted.

4. The observations made in this case suggest that attacks of pain of paroxysmal incidence and the distribution and character of angina pectoris may be initiated by esophageal spasm.

MECONIUM ILEUS

E. W. ADAMSON, M.D., AND JACK R. HILD, M.D., DOUGLAS, ARIZ.

In 1919 a case of intestinal obstruction in a newborn infant, caused by inspissated meconium, was described by Bullowa and Brennan.[1] Hughes[2] described a similar case in 1922. Since then, others have described the condition; Dodd[3] in 1936 reported the twenty-second case and gave a summary of the cases previously described. In six cases, including her own, necropsies revealed pathologic changes in the liver or pancreas, affecting the secretion of bile or pancreatic juice. Lack of either of these secretions was thought to be the causative factor.[3] The terms "meconium ileitis" and "meconium ileus" are both used as descriptive of the condition. The latter seems more appropriate.

REPORT OF CASE

The case here reported is one of meconium ileus and, in addition, presented an ileocolic intussusception that undoubtedly had existed before birth:

An infant girl was the third living child born to a healthy mother by spontaneous delivery. The mother was in labor one hour and ten minutes after entering the hospital. The previous children were living and well. Nothing abnormal was observed in the infant until thirty-six hours after birth, when she refused to nurse and began to regurgitate freely, with much mucus in the vomitus. An enema was attempted and a jelly-like substance with some blood was obtained by rectum. It is to be noted that up to this time no bowel movement had occurred. Colonic flushing was repeated, only a small amount of mucus and blood being obtained. The nurse then noted that the abdomen was hard and distended, with visible peristaltic waves. Physical examination revealed no other abnormalities. A diagnosis of intussusception with complete obstruction was made and immediate laparotomy was decided on.

Thirty-eight hours after birth the baby was taken to the operating room. Under local infiltration with 0.5 per cent procaine hydrochloride a lower midline incision was made. The last inch of the ileum was found invaginated into the cecum and many dense adhesions bound the inner and middle layers of the intussusception firmly together. It was reduced with some difficulty. The ileum showed marked enlargement for about 18 inches above the ileocecal junction, the distention being due to a dense mass of putty-like consistency which it was found impossible to move. The distended ileum was opened and an attempt, which failed, was made to remove the contents. The mass was composed of yellowish meconium with a consistency of thick wax. A catheter was purse-stringed into the enterostomy and the wound partly closed.

Following operation there was continued regurgitation and nothing but bloody mucus was obtained by colonic flushing. There was no drainage from the enterostomy tube. Death occurred twenty-one hours after the laparotomy and fifty-nine hours after the baby was born.

COMMENT

This case is unique in that there was really a mechanical obstruction as well as "meconium ileus." The adhesions binding the inner and middle layers of the intussusception together were so dense that it was impossible to decide on the length of time it had existed, except in a general way. It seems safe to say that the adhesions were much more than thirty-eight hours old at the time of operation.

The relation between the intussusception and the distended ileum, filled with waxlike meconium, is not clear. Since twenty-two cases of meconium ileus have been reported, with no evidence of other cause of obstruction, it would seem plausible to assign a secondary role to the intussusception—the result of violent peristaltic movements attempting to move the mass of waxy, inspissated meconium.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

ALOE SHORT WAVE UNIT, TYPE CSC, ACCEPTABLE

Manufacturer: A. S. Aloe Company, 1819 Olive Street, St. Louis.

The Aloe Short Wave Unit, Type CSC, is recommended for medical and minor surgical procedures. It is similar to the Council accepted Aloe Short Wave Diatherm, Type CSW (THE JOURNAL, Sept. 4, 1937, p. 793) except for the addition of an inductance cable outlet, thus providing for coil, cuff and pad technics. The semiportable walnut finished unit with side handles is available with a walnut cabinet or chrome stand.

Schematic diagram of circuit.

Generating a 12 meter wavelength, the unit utilizes two tubes in a self-rectifying, push-pull, tuned plate, tuned grid oscillating circuit. The output circuit is inductively coupled to the plate circuit and is controlled by a variable air condenser in series with one patient terminal. The electrical parts are licensed under patents owned by the Electrical Research Products, Incorporated. (Cuff electrodes are manufactured under patent 2,110,392.)

Transformer temperature tests were carried out on the unit by an investigator for the Council. The machine was operated for a period of two hours under a load of 250 watts as measured by the lamp load. The final temperature of the transformer was 93 C. by the resistance method and 80 C. by the thermometer method. A power input of 750 watts was required and the electromotive force across the line was 110 volts. The final temperature by the thermometer method comes within the limits of safety. The firm submitted data concerning power measurements made by the calorimeter method.

In addition, the firm submitted evidence to support the ability of the unit to generate heat deep within the tissues. In the cuff technic the electrodes were made of a stiff resilient metal so that they embraced the thigh with a springlike action. The dimensions were 2⅜ by 25 inches (upper cuff) and 2⅜ by 18½ inches (lower cuff). The metal strip used in the electrodes is 1½ inches wide. The average distance between cuffs was: right, 7¾ inches; left, 7½ inches. Average spacing was: right, 1 inch; left, ⅞ inch. Room temperature was 74 F.; humidity was about 42 per cent.

Average of Five Tests by Calorimeter Method

Line voltage	120 volts
Plate current	360 milliamperes (2 tubes)
Input	996 watts
Output	402 watts

When the coil technic was tested, the distance between each coil was approximately 1 inch. About one-half inch of spacing was used to separate the coil from the skin. The average thigh circumference was about 19¼ inches. The room temperature was approximately 75 F., the humidity around 48 per cent.

The unit was tried out clinically by a qualified investigator, who reported that the apparatus gave satisfaction when used for cuff and coil technic.

Average Temperatures of Six Observations

Cuff Technic			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
97.3	107.3	99.0	99.2
Coil Technic			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
98.7	105.7	99.7	99.8

In view of the foregoing report, the Council on Physical Therapy voted to accept the Aloe Short Wave Unit, Type CSC, for inclusion in its list of accepted devices.

MARTON GALVANIC APPARATUS NOT ACCEPTABLE

Manufacturer: Tremont Laboratories, 110 West Fortieth Street, New York.

The Marton Galvanic Apparatus is designed primarily for the removal of hair, although units are available for iontophoresis as well. Duplex units supply currents for both procedures, whereas Simplex units deliver current only for depilation. Both types are available in cabinet or portable models. Standard equipment includes one dozen insulated electrodes, arm-band indifferent electrode, a multiple electrode holder, and cords to accommodate twelve needles.

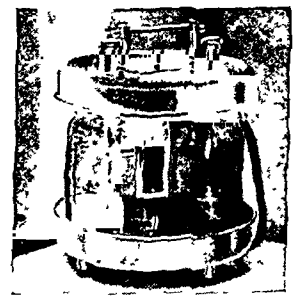
The firm claims that the use of an insulated electrode with blunt point offers a fundamental improvement over older types of equipment. Thus, to aid the operator in gaging depth of penetration, a coating of contrasting color is superimposed on the electrode shaft reaching to within 2.5 mm. of the blunt end. The manufacturer claims that the blunt point enables the operator to maneuver the needle into the hair follicle more readily thus preventing its penetrating farther than the hair bulb. The insulation reaches to within 1 mm. of the end of the electrode, so that the current is concentrated at the point of application in the bulb, without destruction of surrounding tissue, according to the firm.

The manufacturer claims that twelve electrodes may be used at the same time by means of a multiple electrode holder consisting of a head band with twelve needles attached; that this band is attached to the patient; and that if the patient's head moves slightly the needles are not pulled from place.

The unit operates on ordinary house current, either direct or alternating. It supplies an unfluctuating, nonirritating, smooth current, according to the firm. An automatic time switch is included. This turns the current on after the needle has been inserted and turns it off after the set period of exposure has elapsed. The firm states that two minutes will generally suffice.

The unit was investigated in a clinic acceptable to the Council and was reported only fairly satisfactory. The investigator reported that insulated electrodes are not new to the profession.

One advertising pamphlet was submitted, "Superfluous Hair blights the happiness of many a woman." The advertisement contains several questionable statements. "Galvanic depilation originated for ingrown eyelashes. Unsuccessful in hypertrichosis"; "Depilation by the galvanic needle . . . more likely than not resulted in a permanent disfigurement worse than the original." In the opinion of the Council, it is the operator rather than the machine that is responsible for scarification, if present.



The advertisement reads that "courses are given by expert instructors." If individuals take short courses in the technic of depilation and they do not operate under the direction of physicians, such individuals may do much harm.

In view of the foregoing report, the Council on Physical Therapy voted to reject the Marton Galvanic Apparatus for inclusion in its list of accepted devices because the unit did not perform satisfactorily and, in addition, the advertising matter distributed with it contains misleading, unwarranted or exaggerated statements.

WISCONSIN OXYGEN HUMIDIFIER ACCEPTABLE

Manufacturer: Scanlon-Morris Company, Madison, Wis.

The purpose of the Wisconsin Oxygen Humidifier is to add sufficient water vapor to oxygen administered by the oropharyngeal catheter method to supply moisture to the mucous membranes. It is equipped with a water gage to register the flow in liters per minute. The equipment consists of three quart-size mason jars resting on a metal tray (9 inches in diameter with one-half inch edge) with a similarly shaped cover bolted to a center stem to hold the jars in place. A convenient carrying handle is supplied. Quart-size mason jars are used, to permit quick replacement in case of breakage. These jars screw into standard tops fastened to the cover of the humidifier. Metal parts are chrome finished. Rubber tubing connects the humidifier to the oxygen tank and to the catheter.

Wisconsin Oxygen Humidifier.

The pressure of the tank oxygen is reduced by means of the Linde Oxygen Therapy Regulator, Type R-51 (accepted by the Council on Physical Therapy, THE JOURNAL, June 9, 1934, p. 1941). The oxygen then passes through the humidifier jar, which has been previously filled with water to a marked level. Here a mixing chamber containing porcelain beads breaks it into fine bubbles calculated to pick up all the moisture possible. In the next jar there is a water flow gage to serve as an additional check on the cylinder flow gage, indicating the approximate flow in liters per minute. The firm claims that the additional gage is important because the spring type may still register flow in spite of complete obstruction, whereas the water type indicates no flow under similar circumstances. A third jar is provided to trap any excess water droplets so that they will not be carried to the patient. The flow gage jar and the humidifier jar are equipped with filling cups to permit ready replacement of water that is removed by evaporation.

The unit was submitted to a qualified investigator appointed by the Council. The evidence submitted by the firm was examined carefully and the device was tried clinically and found to give satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to include the Wisconsin Oxygen Humidifier in its list of accepted devices.

ABDOMINAL SUPPORTS, CORSETS, SPECIAL SUPPORTS AND TRUSSES

At its annual meeting, January 13-14, the Council on Physical Therapy discussed the question of further consideration of abdominal supports, corsets, special supports and trusses. After due deliberation, the Council voted to discontinue its activity with regard to these products. It was pointed out that certain fundamentals about the construction and fitting of these products are not given careful attention and that such devices, useful for therapeutic purposes, should be prescribed individually.

In the opinion of the Council, the therapeutic value of these products is achieved only when they are fitted properly to the individual patient from an anatomic and physiologic point of view. It was the opinion of the Council, after careful deliberation, that corsets and abdominal supports, as they are now sold and fitted, do not receive the attention of specialists and that the therapeutic purpose for which they were originally considered by the Council has been lost sight of.

Therefore the Council will no longer give consideration to various makes of abdominal supports, corsets, special supports and trusses (effective at once) but will sponsor a series of articles relative to the use of these appliances from the standpoint of orthopedic surgery. The Council will ask those firms having accepted products to delete the seal or any mention of Council acceptance from their advertising matter and descriptive literature by Jan. 1, 1940.

PYREXON INFRA-RED HEAT RAY APPLICATOR NOT ACCEPTABLE

Manufacturer: Pyrexon Ray Corporation of America, 331 Fourth Avenue, New York.

The Pyrexon Infra-Red Heat Ray Applicator was submitted for consideration of the Council on Physical Therapy by the Pyrexon Ray Corporation of America. The heat applicator is a relatively small portable baker for use in the home or hospital. The Home Model measures approximately 16½ by 12 by 5 inches. It weighs about 6½ pounds. The heating element is concealed in a housing consisting of copper sheeting stretched across a wooden frame with asbestos protective covering between wood and copper, and also between copper and the patient. The firm states that this type of covering prevents baking or scorching the skin and permits the heat to penetrate into the tissues without much surface effect.

There is a two coil heating element, one part rated at 100 watts, the other at 75 watts and both at 110 volts. The power input is approximately 175 watts at full load. One of the coils is attached to a thermostat, which is calibrated at 145 F. It is placed on top of the thin insulated packing. The thermostat cuts off the 75 watt coil, thus leaving the device running on 100 watts when the temperature becomes too high.

Physical data presented by the firm indicate that the burners generate infra-red radiation at approximately 85,000 angstroms in wavelength.

In the advertising pamphlet submitted, "Presenting the Pyrexon Heat Applicators for Home Use," it is recommended for use in cases of sciatica, lumbago, neuritis and contusions. Critical evidence to support the efficacy of this device when used therapeutically to treat these conditions has not been submitted.

The baker itself was investigated in a clinic acceptable to the Council. The report stated that the baker must be in contact to secure necessary heating and that heating effects were not as comfortable as with other bakers. The supporting legs were not secure.

In view of the foregoing report, the Council on Physical Therapy voted not to include the Pyrexon Infra-Red Heat Ray Applicator in its list of accepted devices because the unit is not an efficient heater and it is advertised in a manner which is not in the interest of the public welfare.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry of the American Medical Association held its thirty-fourth annual meeting at the Association headquarters Friday, March 17, 1939. Those in attendance were Drs. David Barr, J. Howard Brown, S. W. Clausen, H. N. Cole, C. W. Edmunds, Morris Fishbein, E. M. K. Geiling, Ernest E. Irons, Paul Nicholas Leech, Perrin H. Long, G. W. McCoy, Stuart Mudd, E. M. Nelson, W. W. Palmer, William C. Rose, Elmer L. Sevringhaus and Torald Sollmann. In addition, the following members of the Council on Foods attended the meeting: Dr. George R. Cowgill, Dr. James S. McLester, Dr. Tom Spies and Dr. Franklin C. Bing.

Dr. Torald Sollmann was reelected chairman of the Council and Dr. W. W. Palmer was reelected vice chairman.

Among the many items discussed, the following may be of interest both to physicians and to manufacturers:

Liver Preparations.—Standardization of liver preparations, both U. S. P. preparations and nonofficial preparations, was the subject of discussion. The Council voted that a suitable statement of standards referring to the method of determining potency under the auspices of the U. S. P. Anti-Anemia Preparations Advisory Board be prepared with a view of substitution for the detailed descriptions now appearing in New and Nonofficial Remedies.

Antiseptics and Disinfectants.—The referee for antiseptics discussed the necessity of informing the medical profession concerning the new evaluation of bacteriostatic powers of the mercurial preparations. It was found that many of these preparations, investigated in the laboratory of one of the referees for the Council, would not kill bacterial spores within twenty-four hours' exposure under relatively ideal conditions. Since these bacteriostatic substances are not bactericidal in the pure state it would not be expected that they would be more active in the presence of organic serum. This led to further investigation, on which the conclusion has been reached that such products may have distinct usefulness because they are highly bacteriostatic and will prevent growth, are good preservatives in biologic products and may even be good antiseptics, when that term is defined as something which is not necessarily highly germicidal. They may be considered to have "disinfectant" rather than "germicidal" properties. It seemed probable that phenylmercuric subnitrate, in which the mercury is attached apparently to a different ion, has essentially the same degree of activity as the other mercurials.

The topic of inadequacy of phenol coefficient tests for the evaluation of antiseptics or disinfectants was presented to the Council by one of the referees. It was pointed out that the following paragraphs from circular No. 198 of the United States Department of Agriculture has frequently been overlooked by those interested in evaluation of bactericidal and bacteriostatic agents:

> There are certain types of germicidal agents, such as many of the mercury compounds, which give very high results by phenol coefficient tests. Due to the high inhibitory value of such substances in preventing growth in the subcultures, these figures are frequently misleading. For germicides used in the disinfection of such objects as surgical instruments, this is of particular importance and must be taken into account. Failure to appreciate this characteristic of certain compounds is much more likely to lead to error when Staphylococcus aureus is used rather than Eberthella typhi as the test organism. That false values may not be obtained for products of this type, or for any other disinfectant giving suspiciously high results, the subcultures should contain very large amounts of medium or they should be retransferred by carrying at least four loopfuls from the first subculture to a second tube of broth, as recommended by Shippen.
>
> Other groups of disinfectants in common use, for which the phenol coefficient method of testing is not well adapted, are those compounds containing chlorine as the active agent as well as oxidizing agents in general. These are affected so materially by the presence of organic matter that a phenol coefficient statement may grossly misrepresent their value under practical conditions of use and is very apt to be misleading to the consumer when placed on the label.

In the case of mercurial disinfectants an unduly high and misleading phenol coefficient is given, because the retransfer method was omitted. The same is true of certain silver compounds. It was further pointed out that any bacteriologic tests for mercurial compounds and the like alleging bactericidal properties should be made under conditions of actual application to supplement a test under simplified and arbitrary conditions. For instance, it has been found that mercurials are rendered completely inert bacteriologically by the addition of relatively larger amounts of normal horse serum, and therefore to get a therapeutic result in serum would require many times the lethal dose of a mercurial.

In view of this discussion the Council voted that a further statement be published at a later date reemphasizing that the phenol coefficient is an inadequate basis for judging the antiseptic value of nonphenolic agents and needs to be supplemented by tests under conditions of actual use. It was also pointed out that the same necessity for evaluating antiseptic substances in every possible way by at least approximating the actual conditions of use applies also to various dusting powders. Some of the well known nonaccepted dusting powders were found by tests to be wholly inactive under certain conditions when tested by more critical methods.

The word "preservative" was defined by the Council (for purposes of declaring the presence of preservatives on the labels of serum and vaccines and the like) as follows: "a preparation present in, or added to, a product for the purpose of destroying and/or inhibiting the multiplication of micro-organisms."

Revised Edition of Glandular Therapy.—The Council considered radical revisions of the book on glandular therapy, par-

ticularly in view of the newer advances in this field since the first edition, published at the close of 1935. The Council authorized the editorial committee to confer and to ask various authorities in respective fields to cooperate in this matter.

Digitalis.—The matter of digitalis, and particularly the use of such terms as "digitalis unit," "cat unit" and the like received attention. The Council voted that the subject be given further consideration.

Contraceptives.—The Councils' Committee on Contraceptives reported progress in the consideration of this subject. The report of this committee appears in the annual Reports of Officers (THE JOURNAL, April 8, p. 1358).

Labeling of Vitamin Dosage in Terms of Drops.—It was brought out that the drops of vitamin preparations of various manufacturers vary considerably because of the various types of droppers with the preparations. It is therefore hard to make comparative estimates of the relative potency of the products in terms of the prescribed dosages. There has been a tendency on the part of some of the manufacturers to exploit the claim that their bottle of vitamin preparation holds more drops than other bottles. To overcome in part this tendency, the Council voted that the label of liquid preparations containing vitamins should indicate the correct unitage of the product in terms of units per gram, or per cubic centimeter, as may be proper, and in addition that the approximate number of units yielded by a drop from the dropper provided be indicated.

Thiamin Chloride.—The Council voted to recognize the higher unitage for thiamin chloride, namely, a gram of crystalline thiamin chloride (crystalline vitamin B_1 [hydrochloride]) contains 333,000 U. S. P. units. The Council, therefore, announces that it will recognize claims for this unitage for the crystalline substance.

Proposed Names for New Vitamins.—The Council again pointed out the necessity of careful choosing by investigators of new names for vitamins which will not conflict with the rules of the Council on nomenclature, particularly with regard to therapeutically suggestive names. The Council has arranged for cooperative consideration with two scientific societies concerned and trusts that when scientific names are coined for such vitamins as vitamin K and others after the substance is isolated the selection will be one of an acceptable type.

Barbituric Acid and Its Derivatives.—The Council was asked by the House of Delegates to report on certain matters in reference to barbital and barbital derivatives. The first report has already been published in THE JOURNAL ("A Study of the Promiscuous Use of the Barbiturates," April 8, p. 1340). There is in preparation a second report on data collected from hospitals in various cities. The report will give information as to the reasons for addiction, duration of the addiction and frequency of use. It was pointed out that there are still certain data needed before the second report can be published.

Medical Patents.—The Council discussed informally the conference on medical patents held previously but took no action.

Pharmacopeial Convention of 1940.—It was called to the attention of the Council that the pharmacopeial convention will be held in 1940. It was thought advisable that THE JOURNAL emphasize at an appropriate time the importance of the medical profession's participating in the pharmacopeial convention and that this importance be stressed to the various medical schools and universities and other groups that send delegates to the convention; that there is need for revision of the methods of the pharmacopeial convention. It should be further emphasized that the Board of Trustees of the American Medical Association has authorized adequately close cooperation with the board of trustees of the U. S. pharmacopeial convention with a view to correcting some of the undesirable features which were noted in the convention in 1930.

Crystalline Zinc Insulin.—The Council discussed extensively the complex problems concerned with this subject. Certain important actions were taken which may be the subject of a separate report.
